CHILDREN,

OF

AND THEIR

REMEDIES.

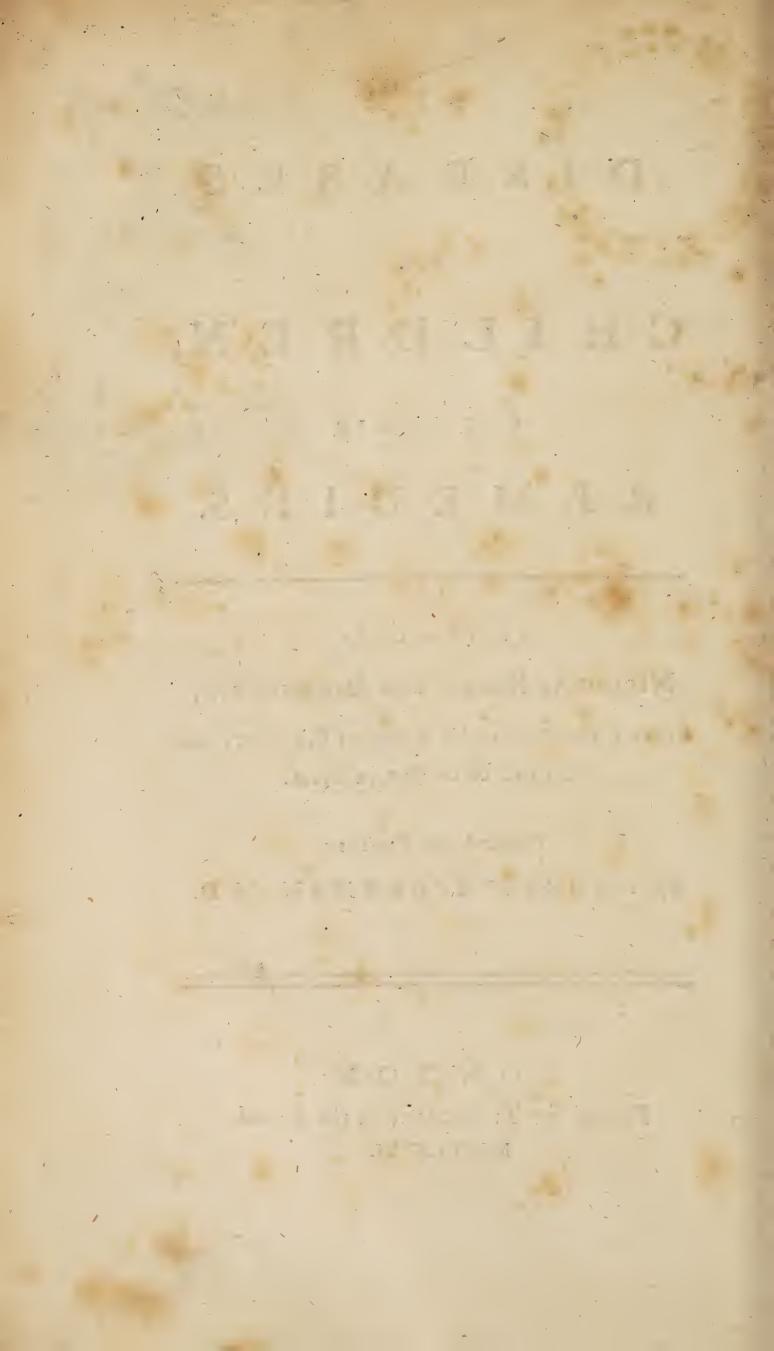

BY THE LATE

NICHOLAS ROSEN VON ROSENSTEIN,

FIRST PHYSICIAN to his Swedish Majesty, and KNIGHT of the Polar Star.

Tanflated into ENGLISH By ANDREW SPARRMAN, M.D.

L O N D O N : Printed for T. CADELL, in the Strand. MDCCLXXVI.

#### THE

# AUTHOR'S PREFACE.

THE Royal Academy of Sciences having been pleafed to order my writings on the Difeases of Children, to be printed gradually in their Almanacks, are now defirous of feeing them together in one Work, thinking by this means to render, the public fome fervice, especially as the first year's Almanacks are not now to be had. Had it not been the defire of the Royal Academy of Sciences, I should not have prefumed the undertaking of fo nice a task, as the composition of this little work. But the refpect I owe that learned body, together with the benevolence with which the public have received my Effays in the Almanacks, encouraged me to continue in the fame manner with every other difease incident to Children, fincerely wishing by this means, to be of fervice to my country, and also to answer the intentions of the Royal Aca. demy of Sciences.

# TRANSLATOR'S PREFACE.

THIS work on the Difeases of Children is translated from the newest Swedisch edition of the year 1771, that being the language in which it was originally written.

The Author, lately deceafed, Archiater N. Rofén von Rofenstein, ennobled and knighted, and, what is still more, universally admired and beloved for his merit in the physical science, was the oldest and most experienced practitioner of physic in Sweden, and favoured the public with the present performance at the defire of the Royal Academy of Sciences; he being especially famous for his great knowledge of, and fuccess in curing, the diseases of children.

The cures here laid down are founded not only on the Author's own extensive practice and reading, but also on a number of practical observations communicated to him by other eminent physicians of the metropolis and the provinces of *Sweden*; many of these gentlemen having been the Author's pupils when he was formerly profession at *Upfal*, and having had the opportunity of confulting him ever after his being called from the university to court, which happened many years ago.

The

The judicious Reader himfelf will eafily perceive the treatife very well deferving the high encomium it is diftinguished with by the famous Dr. *Tiffot*, professor *Baldinger*, and several others.

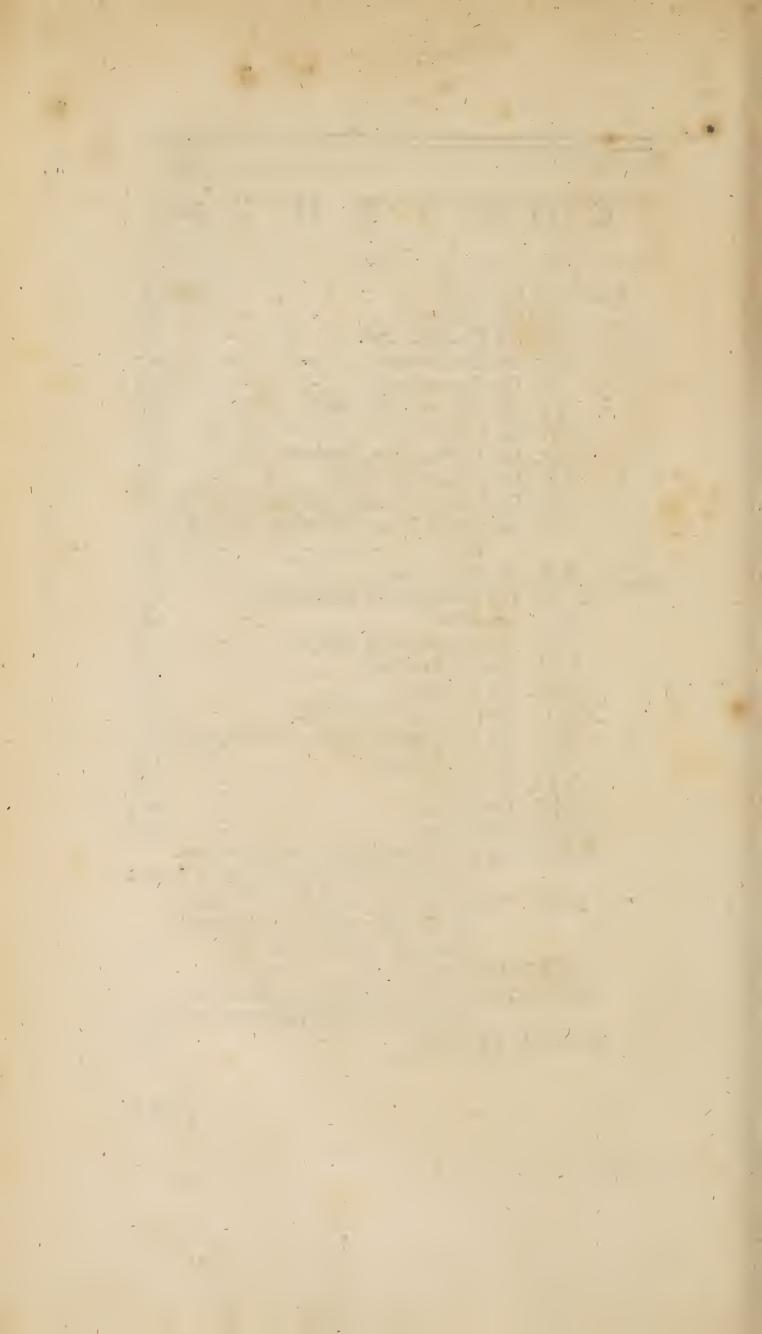

The worthy Author has made the Swedish original of more univerfal use to his country by rendering his work intelligible even to people of an ordinary capacity; the Translator has likewise endeavoured to make its utility equally extensive among the English public. May it therefore prove beneficial to British children, a comfort to their parents, and conducive to the happiness of mankind in general!

# DISEASES OF CHILDREN,

#### A N D

#### THEIR REMEDIES.

#### CHAPTER I.

#### ON NURSES.

CHILD ought to get a fufficient quantity of good nourifhment, if it is to thrive well. The best food for it is, no doubt, the mother's milk. We therefore find, that children thrive well, fuckled by their mothers milk, tho' that fhould not ftand all the proofs which are required towards approving that of a nurfe. Thus, if another child fhould fuck the fame milk, it would immediataly grow fick. For this reason then, mothers ought to suckle their own children; by this they gain a great deal : they will at least have easier-deliveries, avoid feveral difeases, as the milk-fever, purpura puerperarum, and inflammation of the womb, by a translation of the milky matter; also bubones lasteæ in the groins, which often makes them lame. They avoid likewife the fluor albus or whites, which often arife from fuch causes. Vide Mr. Faber, lib. cit. p. 65. These motives ought to induce the mother to fuckle the child herfelf, at least during those weeks she is obliged to stay within doors, efpecially as the mother's milk carries off B

off the *meconium* better than any thing, frees the child from many diforders, and makes it acquire her own temper and difposition. Therefore we fee, that young lions who have fucked a cow or a goat, have by this means been as it were tamed : and dogs on the contrary, who have fucked a fhe-wolf, have become beafts of prey.

But fhould it happen, that the mother has no milk, her nipples either being too fmall, or too large, too thort, too hard, or too tharp pointed, that the child cannot hold them fast in its mouth to fuck them : or if the thould have fore ones, or herfelf be too fickly or weak, having the confumption, gravel, or any other diforder, by which the milk thus affected might be propagated to the child : or if the is of a temper too eafily moved by joy or forrow, or in a fituation where the cannot avoid being often exafperated : then the oughtnot to fuckle her child, but procure a good nurse for it. Such a one ought to be naturally of a ferene, chearful, sweet, and virtuous disposition. She ought to be between 20 and 30 years of age, to have lain-in a little before the child's mother, and alfo to be used to the nurfing of children; the ought to be of a ftrong conftitution, and not afflicted with any hereditary difease, that might be transferred to the child : free also from the fcurvy : therefore her gums ought to be well examined, whether they are hard and firm. But above all other things, care should be taken, that she has not any venereal diforder, scabs, herpes, hard glands, &c. as these are indications that her humours are corrupted.

A fat nurfe is preferable to a lean one; but if one can be found, that nearly corresponds with the conftitution of the child's mother, fhe will answer still better; she ought to be able to suckle the child at each breass, the nipples of which should be of a middling fize. These ought also to be irritable, fo that they grow crect by being gently stroked with your singer, which is a necessary quality to their giving milk. She ought to have good milk, and a sufficient quantity of it.

Its goodness may be tried,

1. By its colour, which ought to be white or rather bluish.

2. By

2

2. By the fmell, as it fhould be void of any.

3. By the tafte, which ought to be quite fweet, and not by any means falt or bitter, or in the leaft fimilar to that of a cow that has just calved, changing to what is commonly used. Its most healthy taste is like cows milk diluted with a little water, and sweetened with a little fugar.

4. By its confiftence, becaufe when thin it is always better than when thick : therefore a drop of it on your nail, ought eafily to run off on inclining it : even on fhaking the finger haftily, there ought not to remain the leaft white ftreak on your nail.

5. By the touch, becaufe not any pain ought to be felt, on letting a drop of it fall into the eye.

6. With rennet, for if the milk gives much cheefe on coagulating it, you may judge it to be good for nothing.

7. By keeping it for feveral hours in a glafs, becaufe if it then gives much cream it will also prove bad. The fame is to be observed upon weighing the milk, for the more cream it gives the lighter it will be found.

8. By the age, because the older the milk is, the thicker and more unhealthy it will be; therefore, when the choice of two nurses can be made, the one of 30 years of age, and her milk one month older than that of the mother, and the other at the age of 20 years only, and her milk 6 or feven months old, we then ought to give the preference to the first, provided they both agree in other circumstances. If we cannot procure any nurfe, and the mother cannot fuckle her child, then we must accustom the child to suck by means of a little inftrument, or fucking bottle (called Biberon), which is univerfally used in Easter-Bothnia with great advantage; but this machine ought always to be kept clean: it is to be made of horn, the smaller end of which may be fastened to a tanned skin of a cow's teat, or if that is not to be procured, we may use any other thin skin, pierced with many fmall holes. Pour in this as much cows and goats cream (unboiled) as you think the child will use at once, dilute it with water, and fweeten it with a little B 2 Jugar.

3

A

fugar. As the child grows older, we may give it more food, as shall hereafter be mentioned.

It is not only neceffary to procure a nurfe with the above-mentioned qualities, but she ought also to obferve a healthy and regular diet, in order to make the child thrive better; therefore it is necessary that she should have a large and airy chamber, free from any draught of air; it ought to be equally and tolerably kept warm, often fwept clean and neat, in order to avoid any bad fmell, as alfo to prevent the nurfe and the child from getting the itch ; fhe ought not imprudently to expose herself to the cold; and except when it cannot be avoided, she ought always to cover her breafts very well, and if they fhould at any time grow cold, then fhe ought to omit fuckling the child until they are grown warm again, otherwife the child will get the catarrh at the nofe, and cough : however in my opinion, fhe ought not by any means to keep continually in the chamber with the children; on the contrary, she ought to have free access to the other rooms whenever she pleases, and there perform any kind of gentle exercife. I have myself known the milk of a good nurfe spoiled by fuch a confinement, which by moderate exercise in the house, from one room to another, was reftored again in a fortnight's time. She ought to have a fufficiency to eat, and that at certain hours : small beer may be drank at pleafure, but this fhould be neither four, new, or stale, and not to be drank, by any means, when drawn over night. Wine, brandy\*, ale or coffee, ought by no

\* A child perfectly fresh and healthy, and having also a healthy and chearful nurse, thrived always very well in town, but when it was sent to pass the summer in the country, it grew weak and fick every Sunday: I could not conceive the reason of it, thinking the nurse lived on those days, the same as on other days: she never got brandy to my knowledge, as is customarily given in Sweden to other servant-women; at last I found out, that some of her fellow-fervants gave her part of theirs, which being prevented, the child was as well on Sundays as on the other days.

means

#### AND THEIR REMEDIES.

means to be given her; tea fhe may drink with milk, but feldom; the veffel out of which fhe drinks, ought every day to be cleaned, and to be made of ftone, rather than any thing elfe. Some are ufed to put melaffes in the nurfe's drink, but I have known it occafion a great flux to the children. With refpect to food, there is no occafion for fo great a nicety; the food which the nurfe is most accustomed to, and likes the best, is generally the most fuitable; she ought not to eat any thing four, or feasoned with onions or garlic; but if she eats any pease, turneps, or cabbage, the child will generally be troubled with wind.

The nurfe ought every day to have a ftool, and immediately to let you know if fhe is coffive, which ought to be remedied as foon as poffible, by a fuppofitory prepared of two drams of honey and half a dram of falt; this is to be dipped in oil of olives. We never dare give purges to a nurfe, becaufe if her breafts are full at the time fhe takes the purge, and fhe a little time after is obliged to fuckle the child, the medicine will have no effect upon her, but purge the child, which generally by this means lofes its life. If the nurfe gets a flux, you give half a dram of rhubarb, and eight hours after if neceffary, a fmall teafpoonful of *Elect. e fcordio*; but in the interim we muft prepare fome other food for the child.

A nurse who suckles, hardly ever has her menses at that time; but if they fhould appear, they will generally be accompanied with gripes : I have evidently found that children fucking on those days have been indisposed; therefore it would be much safer, if some other perfon fhould fuck the nurfe's milk on those days, and the child in the mean time, to be fed with clear whey, which is to be prepared of coagulated milk and eggs: fuch whey I mean, as we get in preparing egg cheefe; this as well as all other food for children ought to be well covered over, that no infects or any fuch thing can get at it; therefore it would always be of fervice, to accustom a child early to other food. It may feed on what is already mentioned, while in its infant state, and that principally by way of the above-mentioned fucking-horn; afterwards we may give it milk (unboiled), which should B 3

6

should be diluted with barley-water, provided the child has any flight fever. If the child is difpofed to obstipations, mix the milk with a little thin oatmealgruel filtrated, in which diffolve a little clarified honey; meal pap is never to be given to any child, it is too gluey, tenacious, and flimy a food, and caufes obstructions in the mesentery, hardness of the stomach, acidities, wind, and many other indifpofitions, by which means we lofe at leaft the one half of our children. Mr. Mauriceau's 263d observation, and that of Dr. Zimmerman at Zurich, proves this sufficiently \*. When the children are half a year old, we may begin to give them unboiled milk, in which we have mixed a little rye-bifcuit, which is tender and well fermented, being previoufly foaked in warm water. The nurfe ought to avoid all commerce of love, because the child will fuffer by that: the milk by this means, will be fpoiled and grow falt; therefore a married nurfe ought at that time to have no connections with her hufband. If we discover in her fuch an inclination, the is then no longer fit to be a nurfe : and the fame is to be observed, if the is big with child.

Exercife is indifpenfably neceffary to a nurfe, if we wifh her to thrive well, and that in her body fhall be prepared a milk which is not too thick, or which too eafily grows acid: for that purpofe, it is neceffary to order the nurfe to take fome exercife, or to put her to fome work; for inftance, to let her grind wheat in a fteel mill, or fome fuch other thing, which will bring on a gentle fweat. The time for exercife ought not to be immediately after taking the food, but fome time before fhe is going to eat.

If the child is very uneafy, fo that the nurfe is prevented from her fufficient and neceffary fleep, fhe will then grow feverifh, her breafts dry up, the milk will turn yellow and bad; therefore a dry nurfe must be called to her affistance, in order that she may fleep 8 hours out of four-and-twenty. She ought to know

\* See also his fine treatife Von der Erfarung, L1. p. 264, where this necessary observation is treated more at large, 1, 2, 3, 4;

how

#### AND THEIR REMEDIES.

how to govern her passions; if she suffers herself to be exafperated, fhe fhould not fuckle the child immediately, as it will grow indifpofed, get convulfions, or fome other dangerous disease, and often lose its life. Dr. Albinus speaks of a child, a year old, sucking its mother, when she was exasperated, the consequence of which was, that the child immediately got an hæmorrhage through the eyes, ears, noie, mouth, intestinum restum, &c. and died; another is to be feen in the number 3 of Convulsions. It is therefore of great confequence, that every one in the house, but especially the dry nurse, does not give any occation for the nurfe to be exafperated, and that we do not fuffer her to fuckle the child before her anger is fubfided, and that fome woman or other has sucked out her breasts, and that the nurse herself has taken in a cup of water the following powder : eight or ten grains of purified nitre, and thirty grains of morfulæ citri: I observed that she ought to let her breafts be fucked by fome other perfon, and not to empty them, according to the general method, as that is not only infufficient, but it also injures her breafts.

If the nurfe happens to be frighted, and the child fucks her, it will then fuffer; in this cafe her breafts must also be drawn off by some other person, after which she should take 30 drops of spiritus cornu cervi succinatus, i. e. spirit of hartshorn with amber, before fhe fuckles the child again, as alfo every kind of fear ought to be banifhed before that time.

In cafe the nurfe fhould be uneafy and hipt, the child will then begin to pine away : we fhould endeavour to find out the caufe of her uneafinefs, and if it cannot be removed, we mult then procure another nurse. If the nurse falls fick, the child ought not to be fuckled, until she is recovered again. In the interim, it may be fuckled by fome other perfon, or fed as before-mentioned. If we are obliged, from one of these circumstances, to change a nurse, we find it is of no dangerous confequence, provided the one that is made choice of, has the above-mentioned qualifications, though her milk should be something younger than the former; but yet that difference ought not to be of more than 6 weeks, otherwife the child

B 4

child would eafily get a dangerous flux. The business of a nurle is to fuckle the child whenever it is hungry or dry, but not by any means fo often as it fhrieks and cries, because by this its little stomach becomes overloaded, its food cannot be digested, and by changing in the ftomach, grows acid and acrid, then caufing vomitings, attended with gripes in the bowels. Nurfes and mothers imagine this vomiting a fign of - childrens thriving well, but we may compare it to that of a full grown perfon, who eats and drinks fo often and in fuch quantities, that he is obliged to vomit feveral times in the day. A nurfe would therefore do well, to use the child to fuck at certain hours in the day, and even then no more than what is neceffary : the may eafily perceive when it wants to be fuckled,

1. From the time it has gone without fuck.

2. If it fixes its eyes on the nurfe, and they feem as it were to follow her wherever fhe goes.

3. If joy sparkles from the child's eyes, when she opens her breafts.

4. By the child fucking her finger on its being put into its mouth.

The nurfe ought not to fuckle the child immediately after eating, as the milk would then foon grow acid in the child's ftomach and occafion gripes; neither ought fhe to fuckle the child before fhe has breakfasted, as the milk would then be a little acrid. Should her milk decreafe, she may drink cows milk diluted with water, in which a few fennel feeds have been boiled; but this will be of no efficacy in cafe fhe is big with child. She ought also to fuckle the child as often at one breast as the other, if she does not, the child will grow crooked; and for this reafon alfo, she ought not to carry the child always on the fame arm. It is likewife neceffary, that the learns to fwaddle right, and alfo taking care not to fwaddle it too hard, especially across its breast and stomach; nor should she by any means forget, that when the child is fwaddled to the right fide, it ought next time. to be swaddled to the left, to prevent its growing crooked. If the child fhould cry or fhriek whenever it is fwaddled, she ought immediately to take it off agam,

again, as it may fo happen, that it is preffed by a fold, or pricked by a pin, or on fwaddling it may have moved its arm out of order \*. The bandage is alfo to be taken off, as often as the child is wet by piffing, &c. otherwife it will be excoriated; and whenever it is fwaddled, the door muft be fhut, that the cold air may not affect it. The moft approved practice therefore, would be never to fwaddle children, which phyficians have demonstrated by very convincing arguments, as has alfo Profeffor Von Schulzenheim, and fome others by laudable examples on their children. Was a full grown perfon obliged to be thus fwaddled, would he not think it a great hardfhip ? But we feem to have no compassion on our innocent children.

The nurfe ought often to change the child's cap, and never put it on a narrow one, by which its head would be prefied and its growth prevented. The nurfe fhould put a piece of cloth under the cap over its fontanell, in order to keep it warm, or rather the cloth ought to be flitched to it: the fame is alfo to be obferved in refpect to that fontanell behind the former one, because that alfo may happen to remain open for fome time.

Dirt on the head of a child, with which it is born, ought as often as poffible to be wafhed off with foap; but this must be done gently; because if it was to lay there, it would at last lay the foundation for nasty scabs. That glutinous substance, which is on its skin, ought to be washed off with warm water; otherwise it dries up, and forms scales.

A flyepy nurse fhould never be fuffered to fit with the child by the fire-fide : many unhappy circum-

\* A child three months of age, on being fwaddled began to fhriek amazingly; an old experienced gentleman being prefent, gave the child feveral red powders of Dr. Michaelis's *fpecificum anticephalicum* one after another; notwithftanding this its fhrieking continued: a young lady of high family being prefent, obferved that the child ought to be unfwaddled; which being done, the child was filent immediately: its right arm was already blue by its being carried on its back, between the folds of the fwaddles.

stançes

#### DISEASES OF CHILDREN,

ffances prove to us the danger with which it is attended. Care fhould likewife be taken, not to caufe any fmell by the coals, by which means children have frequently loft their lives; at leaft they will have head-achs attended with reachings and vomitings: this is to be cured by applying to the forehead linnen rags dipped in warm vinegar of rofes. Those complaints the nurfe may get by heats, may foon be remedied by going into a little colder room, and applying a fod of grafs to her forehead.

When we are obliged to fwaddle a child by candlelight, we should place a candle opposite its feet, becaufe the child always looks towards that place where the candle ftands, and confequently without this precaution, would fquint, was the candle to be placed on either fide of it : if the child while in its tender years, has acquired this bad habit of squinting with one eye, then we may hope for a cure, by covering its other eye for fome months, as that obliges the child to look ftrait forward with that eve it has accustomed to fquint with. When children do not fuck well, our old women fay, that they are tongue-tied, and pretend that the bridle ought to be fnipped with a pair of fciffars. I have never as yet feen any child's tongue tied. The reason of their not fucking well, is generally that the child has gripes, or that the milk has acquired fome bad tafte: but oftener it arifes from fome defects in the nurse or mother's nipples, as before-mentioned, fo that the child cannot keep them fast in its mouth, or fuck the milk out. The child then generally fmacks in fucking them; this defect in the nipples cannot be remedied, therefore another nurse must be procured. If the child, when it fhrieks, does not carry its tongue up to the palate, or to the outfide of the lips, and the point of the tongue is not round but cloven as it were, we then know that its tongue is tied, but in other cafes we may conclude it is not; should an operation be judged necessary for it, it ought never to be done with the nails, but performed by fome experienced man; otherwise one of the blood-veffels near the tongue might eafily be opened, and the blood flow from it, which is not always to be perceived, becaufe

caufe the child fwallows it. Such unhappy accidents may be feen in Mr. Mauriceau's 301 Obfervation, and in Mr. Dionis's Treatife of Operations, p. 626. When the tongue's bridle has been improperly fnipped, it has happened, that children have been fuffocated by turning the tongue round, and carrying it down into the throat. Such accidents are mentioned by Mr. Petit, in the Tranfactions of the Academy of Sciences in France, for the Year 1742.

A child in its infant ftate, hears but little, therefore we ought not to fpeak flow in its room, but rather ufe it by degrees to noife. A nurfe ought alfo with her finger to ftrike backwards and forwards in the child's mouth, principally over the gums; this will afterwards be of great fervice to the teething.

She never ought to keep a young child upright, unlefs its head is supported by something elfe; it ought alfo to lay with its head a little higher than the other part of the body, otherwife it will be fubject to apoplexies : neither ought it to lay a long time on the fame fide, but be turned as foon as it appears uneafy in its fleep or awake. It would likewife be of great fervice to omit that bad cuftom of rocking children, as by that means they grow vertiginous and drunk as it were; the milk likewife coagulates thereby in the child's ftomach; confequent'y the fleep brought on by rocking will do no good. Take away the caufe of this uneafinefs, and good. it will fleep foundly. Our peafants use hanging cradles, whole motion is lefs violent. Mr. Van Swieten (Comment. p. 681), gives an instance of a boy 8 years of age, being put into a cradle by his play-fellows, kept there and rocked violently till he got a violent vertigo, and vomited gall in colour refembling verdigreafe. The cradle or the bed of the children ought not to stand near any stove, fire-place, or near a wall, where a chimney paffes by from any room below, in which a fire is kept : for thereby it would be used to such a warmth, that it would get catarrhs at the nose, on being afterwards carried to the window, or fome other part of the room; the cradle ought alfo to be put in fuch a direction, that a ftrong light may not fall upon the child's eyes. A full

full grown perfon will find it offenfive to his eyes by working on a table oppofite to the window. It is not only neceffary for the room to be kept clean, in order to prevent the child's getting the fcab, but the nurfe ought alfo to keep herfelf neat and clean : likewife the child's linnen, rags, flannels, &c. fhould frequently be fhifted.

In general we indulge a child by fucking till it has gotten all its 16 milk teeth : in this however, we cannot fix any certain time, as a weak child fhould fuck longer than a robuft one. Neverthelefs it ought to leave off by degrees, and as a beginning towards that, fhould only be fuckled in the night time. At laft when the nurfe will wean it entirely, fhe may fmear fome effence of worm-wood on her nipples, which will foon give the child a difguft for fucking.

When the child has left off fucking, it will grow coftive in the beginning, neverthelefs it will eat much, get indigeftions and gripes; therefore we ought to give it fometimes a little manna to fuck, and fometimes alfo of what is commonly called *anima rhei*, which befides the advantage of removing coftivenefs, alfo corrects acidity, and ftrengthens the ftomach and bowels.

Tender children are generally wet behind their ears, though they thrive well in every other refpect. It is dangerous to use any repellent physic against this difcharge of humours, for fear it should then attack the eyes. Such a discharge behind the ears of a nobleman's son, being dried up with an ointment of cerusse or white lead, occasioned its eye-lids to grow fore, and its eyes to redden in such a manner, that I feared the child's losing its sight: but it was cured by a small vesicatory applied behind its ears, and by the red ointment of St. Ives, smeared with a pencil on the margin of the eye-brows.

If we could prevent the fhrieking of children, it would be of great advantage, becaufe much fhrieking may have many dangerous confequences : for example, the blood is retained in the brain, for it can eafily enter the *arteria pulmonalis*, but cannot well get out again; befides the child grows dry in the throat, feverifh, and gets eafily a rupture. The whole art of filencing filencing a child confifts, I. In removing the caufe of its fhrieking; or 2. In amufing it with fomething which ftrikes its fancy, and wholly engages its attention, and makes it forget what it cried for.

Shrieking we may judge to be caufed by a difeafe, if the child's fcrotum is relaxed, or its excrements green, or the linnen coloured by the urine after being dried, or if it is externally affected with excoriations, boils, or fuch other things, of which the nurfe ought immediately to give the parents notice, in order that they may procure it fome relief.

If the child is hungry or dry, it ought to be fuckled.

Should it have fucked too much, it will not be relieved unlefs by vomiting. If it has lain too long on one fide, and is affected by that, it fhould be turned on the other. Care fhould likewife be taken, that it be not too warm in the cradle.

If the child is fwaddled too clofe, or in fleeping has carried fome member into diforder, or has fouled itfelf, it will be quieted by being unfwaddled, fhifted, and dried before the fire, and its feet likewife warmed. Hard fwaddling preffes the blood up towards the head, therefore a child which is pretty fat, always looks the handfomeft when it is unfwaddled.

It alfo fhrieks, on hearing any perfon clofe to the cradle, whofe voice it is not accuftomed to hear; this is foon remedied by the perfons being filent. If the cuftomary time of its dreffing or fleeping is omitted, that omiffion ought the next time to be corrected, as only the fimple neglect of what it has been accuftomed to, then makes it fhriek.

We enquire if the nurfe has her menfes, as we know if the child fucks on those days, it will of course be uneasly. The true reason of this is, that the woman is then more easily moved, or sooner liable to be affected by something, than at another time.

If we can neither find out, or eafily remove the true caufe, then we must make use of the second method, that has already been spoke of; and which is, to shew the child any thing that it is unacquainted with, and either by means of its colour, or glitter-

ing

ing brightnefs, pleafes it; or we may carry it to the window, or to a looking glafs, shake a rattle, tinkle a fmall bell, bite on fome fonorous thing, or fing to it. We may hush it, but never immediately after its having been fuckled. We may also carry it to another room, or give it to any one it is very fond of. If it is a girl for inftance, we fnew it puppets; and if a boy, horfes, &c. carefully remembering against the next time, what had the greatest effect towards pleafing and making it quiet : but above all, care must be taken, that the nurse in secret does not give it philonium theriaca, or fuch foporifics; becaufe children which often get these things grow stupid, crazy, convulsive, and die. From all this, it plainly appears how much the child may fuffer by its nurse. How nice we ought to be in the choice of her, and likewife how neceffary it is for parents to keep a watchful eye on the nurse's conduct. On her constitution depends the child's health, or difeafes, or whether it shall be lame or not. Now in matters of fuch great importance, unless we will merely depend on chance, we should use the means which the Almighty has given us to provide for our children's welfare. For a more circumstantial account of this, fee Professor Schulzenheim's Oration on the Nurfing of Children, spoken before the Royal Academy of Sciences, in the year 1760.

#### CHAP. II.

#### COSTIVENESS.

DURING the first 24 hours after the child is born, we ought not to allow it to fuck, unless from a piece of mullin, in which is contained a little manna, fugar, or an electuary prepared of the fame. By this means, it will have three or four stools a day, for the first three days, which will be very conducive towards entirely discharging the meconium. Afterwards a couple of stools a day will suffice: when the child fucks, these stools ought to be larger in proportion.

14

When a child remains 24 hours without a ftool, we then judge it to be coffive, and ought immediately to relieve it: the fafest method of doing this, is with the above-mentioned electuary, which should be prepared according the Pharmacopæia Wirtenbergica: we may fend for, an ounce of it at a time, and give a tea-spoonful of it to the child every three hours, leaving it off, as we judge it will operate, which may be known by hearing any noife it will occafion in its body. To a child at the age of 6 months, we may give two tea-spoonfuls at a time, and should it after this continue coffive, we must then affist nature by a fuppofitory, which may be made either of tallow dipped in oil, or a raifin freed from its ftones, and afterwards dipped in oil. Children that are hard fwaddled across their bodies, will not have a ftool until they are unfwaddled.

Thin flefh broth goes almost wholly into the blood, but as this is not the cafe with the milk, it will therefore give more excrements; befides children are weak, and their digestive organs less strong. The guts are also proportionably longer than those in a full grown perfon: for this reason then, more will remain in the bowels of what children eat, and confequently make their evacuations larger in proportion than in fullgrown people.

If the nurfe's milk is old, the child will be troubled with gripes, and be coffive. We may fometimes remedy this, by the nurfe eating a pickled fprat in the morning, fo that fhe may drink the more, and confequently her milk will be diluted. If this does not fucceed, we are obliged then to change the nurfe for another, that has younger milk, but not under fix weeks.

If the child has left off fucking, and its difpolition to be coffive ftill remain, we ought to rub daily with a warm hand upon its ftomach and lower part of the belly, give it a little milk, in which we may mix a little oatmeal-gruel and honey, and let it ufe a little exercife immediately after it, to affift nature towards procuring a ftool. This being done for feveral days together in the morning, and always at the fame hour, nature will at laft become habituated

5

to this neceffary evacuation. We only make the cafe worfe, by having conftant recourfe to phyfic, as by that the bowels become infenfible.

Oil, butter, and every thing fat, injures the flomach, diminifhes the periftaltic motions of the bowels, and confequently prevents them from making the neceffary evacuations. The fame is to be underflood of the yolks of eggs, as they contain much oil; we may expect the fame from a nurfe's milk, if fhe is fat. *Haller's Element. Phyfiol.* vi. p. 200. vii. p. 90. & 103. and Dr. Tiffot in his *Avis au Peuple*. Perhaps this is the reafon of their requiring fuch ftrong dofes of purging medicines in Switzerland, as they are much ufed to fat milk there? See Dr. *Tiffot*, 1. 6. P. 573.

# CHÀP. III.

# Procidentia, vel Prolapsus Ani:

WHEN children get a diarrhœa, or loofenefs, it frequently happens, that the *inteflinum* rectum falls out, which if not immediately cured, will become habitual. I never found any better remedy for this, than fomenting the part fallen down with a fine fpunge, dipped in warm wine. Fuligo, or foot from wood, powdered fmall and fifted, will alfo cure it by ftrewing it on the rectum, and by carefully introducing it into the body again. It will alfo be of fervice to fumigate the protruded part with maftix.

Should this difeafe prove obstinate, the best expedient would be always to accustom the child to a high easy chair, whenever it goes to stool, so as to prevent its soot reaching the floor, as the *restum* will not fall out then. The child's parents need be under no apprehension about this, because, in proportion as the child's years and strength increase, this weakness generally disappears of itself.

# CHAP. V.

# PNEUMATOCELE:

HIS, which in children is called a windy rupture, is very eafily remedied by applying to it a piece of flannel or cotton fumigated with mastich, or fomenting the part with cloths dipped in warm white claret and lime water; or by applying to it emplastrum dia-fulphuris Rulandi. The generality of people neglect procuring any remedy for this diforder, under this pretext, that if they are affected by it in their youth, they will be unfit for ftrong labour all their lives after. From this I suppose arises the old faying, that every eighth man has a rupture. Children fhrieking much, will have ruptures, as their omentum is in a relaxed state. Dr. Haller in his Elementa Physiol. vi. p. 378, and also Mr. Arnold in his Memoires de Chirurgie, enumerates those places where a rupture may happen. The furest relief is to be had from bandages well made, and with steel springs.

# CHAP. VI.

#### CATARRH OF THE NOSE.

A Catarrh of the nofe prevents children from fleeping, and makes fucking very difficult to them : those that are exposed most to any draught of air, or too much heated, by their bed places standing too near the fire, will be most liable to this diforder; they will find some relief by anointing their noses with an ointment of marjoram, &c. or by blowing some fine powdered sugar up the nostrils. I never found any thing of such efficacy as the oil of eggs, frequently some state on the nose \*.

### CHAP. VII.

#### GRIPES.

W E imagine children to be griped, when they are uneafy, often fhriek all on a fudden, and violently contract themfelves, kick much, fleep little, and then fmile; the excrements are green, or foon will be fo, and its cloths appear greenifh when they are dried. The excrements have a four ftench, and wind coming from the child, fmells likewife four; if they fhould remain long, the excrements will have a pale yellow colour, and appear very thin, with little

\* If the floppage of the nofe is increased to such a degree, as to prevent the child from sucking, we must apply to its nostrils, a piece of warm linen dipped in a mixture made of

Aquæ Marjoram Z B. Vitrioli Alb. Elaterii Alb. ana gr. ij. M. Dr.

lumps.

lumps. If the child makes more water than usual, or as the faying is, if it bepiffes itself up to its elbows, it will foon be affected with gripes, as probably this is a fign of being costive.

We ought to cure gripes as foon as possible, otherwife they will occafion convultions. It is very remarkable that a child affected with the gripes, refufing to fuck; will by being held upright before the nurse, suck without the least difficulty until it is fatisfied \*. A child that has the gripes, either is or not coffive; in the first of these cases we may relieve it by fome of the abovementioned electuary of manna, and fhould that be too flow in its operation; we may give a clyfter, prepared with fix spoonfuls of milk, four of oil; and a little fugar mixed well together; in the other cafe, fhould the child be fufficiently loofe, we can immediately palliate its pains by applying on its ftomach a cake moderately warm, prepared of oil of olives; yolks of eggs and flour, which may be baked in a frying-pan; or we may melt some of the Balfamus Scherzer in a spoon, spread it on a piece of leather, and apply it to the child's ftomach; but this only gives relief for a few hours. Abforbent powders procure some relief to young children, but it is very difficult to know when we have given enough of them. Magnesia alba, prepared according to the Pharmocopæia Edinburgenfis, is the best remedy, as it corrects the acidity and occasions stools. It may be either taken in almond-milk, fennel-water, or the child's common drink. We ought to give the mother or nurfe a peculiar powder, which is to be prepared of

B. Magnesia Albæ Zj. Cort. Aur. Hispal. Cond. et exsiccat. Sem. Fænicul: dulc: Sacch. Albi, ana Zij. Misce f. Pulvis.

\* The reafon of this perhaps is, that the acidity then runs down from the *cardia*, which has many nerves, and is confequently the more irritable,

C 2

As

19

As this is not difagreeable nor in the leaft affecting, a nurfe may take this during the whole time a child is affected with the gripes: I myfelf knew a nurfe who was obliged to take this for eight months together, morning and night, and if ever fhe omitted it for two days only, the child fell fick of the gripes; it is now four years ago, both are ftill alive, and in perfect health.

To the child itfelf we may give frequently a little hartfhorn jelly, prepared without acid; and every hour or half hour when awake a tea fpoonful of the following milk for children.

B. Aq. Fol. Tiliæ Zij. Cerafor. Nigr.
Ol. Amygd. dulc. rec. & frig. ana Zi. Salis Tartari Dj. Ovi. rec. vitell. Zij. Mucil. Gum. Arab. Zj. M. D. S. Milk for chldren.

We could eafily correct acidities in children, and alfo promote their digeftion, could we by any means prevail upon them to take fmall pills of half a grain each, prepared of fome gall, for inftance, that of eels, to which fhould be added a little faffron; foap would likewife be of greater efficacy, but it is too apt to grow rancid. *Conf. V. Swieten's Comm.* iv. p. 684. and Dr. *Haller's Element. Phyfiolog.* vi. p. 608. on the virtues of gall in general.

The nurfe's diet in these cases ought to be flesh, and thin flesh broths, in which we may diffolve a few yolks of eggs, well beaten. All acid food must be avoided. We should also procure a dry nurse to affist her, so as to relieve her from too much exercise, as by this her milk will be spoiled. Exercise is notwithstanding at all times necessary, so as to occasion a gentle perspiration, and more particularly at this time. I have already observed in the chapter on nurses, an instance of a nurses milk being spoiled in a fortnight's time, meerly for want of exercise, and restored in as short a time by using it moderately. Should this precaution prove insufficient, we then must procure ano-

ther

ther nurse, whose milk is younger than the former, and perfectly void of acrimony.

Gripes are a very common diforder among children of the poorer people, especially in the fummer feafon, as their mothers then live chiefly on four milk, which occasions gripes in the children, followed by convulfions and apoplexy, by which numbers of them lofe their lives. Happily their mothers are at that time, for the most part, employed in either corn fields, meadows, &c. which labour corrects in a great measure the acidity; was not this the cafe, few of their children would escape death : their mothers to remedy this fhould give them as much oyfter-fhell powdered as will lay on the point of a knife, two or three times a day, in a little water, and repeat it, till the green colour and four fmell of the excrements are quite corrected: fhe fhould also have by her always at hand, a gallon bottle of fpring water, in which should be diffolved an ounce of falt of tartar, in order that fhe may take a fpoonful of it two or three times a day, as foon as fhe finds the child affected with the gripes; otherwife if the waits, as is generally done, until convulfions come on, the event will be dangerous and uncertain.

#### C H A P. VIII.

### DENTITION.

A S foon as a child arrives at the age of four months, and becomes then indifposed, we generally suspect its indifposition is occasioned by its teeth, though this oftentimes has quite a different appearance, which not being taken notice of, increases, and gets the better of the child: we ought therefore not to cure it inconfiderately, but make a diligent enquiry into the real cause of the difease, whether it is or is not occasioned by dentition. We may easily know this by the following figns \*.

I. By

\* The first fign Dr. Van Swieten observed, was the upper margin of the jaw increasing in breadth; by the two

C 3

I. By the child's frequently putting its finger, or any thing it lays hold of, into the mouth, or by biting hard upon the nipples of the breaft; the reafon of its doing this, is, to allay the itching which the preflure of the growing teeth occasions in the gums.

2. If the child fpits much, or fwallows its fpittle. In the latter cafe, it will for the most part have reachings or a diarrhœa, which is of great relief in the cutting of teeth.

3. If the gums are tender, fwelled, or already inflamed; the first of these we may know by the nurse's feeling in the child's mouth, and the latter may be seen by looking at them. The child will also feel fome kind of pain or smart by sucking.

4. If the tonfils, eyes, or cheeks, fwell and become red.

Should all these figns be observed, the child is beyond a doubt affected by its teeth, and every thing will happen in the above-mentioned order. When the teeth are emitted one by one, the child's pain will be triffing, but if several pierce the gums at the same time, dentition will be accompanied with sever, anxiety, startings, convulsions in the muscles of the sace and whole body, and sometimes much worse, ending either in a lethargy or death itself. Dentition is both early and easy, when the child is born the full time

two laminæ (of which the jaw confifts) being diftended a little afunder, fo that the tooth might find room to make its exit. See his Comment. iv. p. 745. I have feen children with those figns observed at No. 1. and No. 2. before the teeth came out, and after having recovered from being very fick for fix or feven days before; but three weeks after that I observed a small hole in the gums, thro' which the tooth was protruded one or two days after without any kind of pain. This feems to confirm what Dr. Harris obferves in his Treatife on the Difeases of Children, which is, that dentition has two periods; the one when the laminæ of the jaw begin to divide, confequently extend more the membrane and gums covering their fockets; the other when the tooth is piercing through this membrane and the gums. after. after conception, and of healthy parents; and its mother during her pregnancy has not been fubject to violent paffions, but on the contrary been of a good and cheerful difposition, has eaten good food, and given the child wholefome milk. The more we neglect the abovementioned rules, the more difficult dentition will be, and the child confequently fooner lofe its life. Those which we call eye-teeth (*Dentes Canini*) and those opposite them, in the under jaw, are the most troublefome of all; and more especially if they, as generally happens, fhoot out later than the foremost grinders; as they then must be fqueezed between them and the fore-teeth, which are very often fituated very close to one another.

A tooth before it can shoot out must first pierce the gums; \* in cafe the teeth fhould not be hard enough, they cannot work their way through, or if the gums are too thick, more time will be required for piercing them, as a greater number of fibres are then to be torn afunder, this occasions irritation and pain, both of which caufe a heat in the mouth, a greater flow of humours to the part affected, swellings, inflammations, and reftlefinefs; from this we learn that dentition becomes eafy if we by any means make the gums thin and infenfible, and procure hardnefs to the teeth. The laft of thefe we gain by giving the child wholefome mother's or nurfe's milk; and the former may be done by the nurfe's rubbing her finger gently on its gums in the manner above mentioned. By this means the gums will become fo thin, by the time the child is at the age of three months, that the teeth will fhoot out almost without occasioning the least fensation. I do not write this merely as a theoretical reafoning, but from re-

\* Mr. Bertin is of opinion, that the pain is caufed by the true root of the tooth preffing the nerve, giving ramifications to the tooth. That little bony *lamella* (*diaphragma offeum*) which is between the milk-tooth, and that below it, feems to prevent the former from preffing the latter. See *Euftach. de Dentib.* and *Albini Annot. Acad.* 1. 2

peated

peated experience. It will equally be of fervice, to let the child bite upon a wolf's tooth, or any other hard thing; the only inconvenience this may be attended with, is, that the child by playing with it, may eafily hurt itself in the face, and especially in the eyes; if by neglecting part or the whole of these precautions, dentition already be very difficult, with the above-mentioned bad fymptoms, we must, 1. relax the gums, and 2. prevent as much as poffible the fenfation of pain occafioned by the preffure of the tooth. As to the first, the gums may be softened and relaxed by frequently touching the tumid and pained part with warm honey, fyrup of violets, althæa root, or fome good oil of olives, or of almonds cold drawn; fresh marrow or butter, fresh brains of a hare, or a calf, or any other animal; the more relaxing and aperient to the gums, the better they are.

As foon as the child, from frequent ufe, will fuffer us to finger its mouth, we may apply to the inflamed part a roafted fig, or a fine fpunge dipped in a warm decoction of carrots, or in milk boiled with figs, althæa root, and a little faffron; this is exceedingly palliating, but ought to be frequently changed. Some people are ufed to boil a whole althæa root in honey, and give it to their children to bite on; but if their gums be fo inflamed that they will not bite any thing, and it has increafed fo far as to threaten a gangrene, we muft repeatedly touch the dark red places with honey of rofes, (mel rofarum) in which is mixed a few drops of fpiritus fal. marini. See Van Swieten's Comment. iv. p. 748.

We may diminish that painful fensation, by giving to the child fyrupus è Meconio Ph. Lond. as much as is sufficient to procure it a little reft. But this remedy ought at first to be given by degrees, so that we may find out how large a dose is requisite towards quieting the child, whenever it again becomes uneasy by the pains. As one child requires more or lefs than another, we cannot therefore fix upon any certain dose; we may be fure to avoid all mistakes by giving only half a scruple every half hour, omitting it as soon as it procures relief. If for instance a dram has been used, and the child five or fix hours

24

hours after begins to fhriek and be uneafy, we then know fuch another dofe will procure it reft for the fame length of time. Yet in the mean time we must not omit the application of the above-mentioned emollients, and give the nurse nothing but cooling food and drink. But herein one thing is to be observed, that we give the child a fufficient quantity of *Elestarium de Manna* to prevent its being costive, or now and then to give a clyster for the fame purpose, as costiveness is the only inconvenience arising from taking this fyrup, and as experience teaches us, that a flight diarrhœa is beneficial towards relieving the pains.

Should the difease, contrary to our expectation, baffle all our remedies (though I never as yet faw them fail) the child continually stricking, is feverish, has startings, and convulsive motions in the mufcles of the face, and fuch other figns of approaching convultions, our only recourfe is bleeding, or to apply leeches behind the ears; and if this is insufficient we may give a larger dose of Syrupus è Meconio, or add to it one or two drops of liquid laudanum (well knowing whether the difeafe is still in the beginning) by which means convulfive pains may commonly be prevented; but fhould this likewife prove infufficient, and the gums redden and fwell, they ought immediately to be cut down to the teeth. There is no kind of danger in this operation, provided none of the fibres of the flesh are left across the fummit of the teeth; in which cafe the pain would become still more violent, until it is cut off, which gives inftant relief. The incifion in the gums ought to be frequently fomented with a fpunge dipped in warm wine, in which fome fugarcandy has been dissolved.

As a fibre is often left on cutting the gums, the fame may also happen by the teeth themselves working their way, though we suppose the tooth to be emitted, although the child is fick as before, but upon a more minute examination, a fibre will be found to stop the progress of the tooth; this being cut off, the pains are relieved immediately, and without doing this, the child might have lost its life.

As

As beneficial as a gentle diarrhœa is on thefe occafions, it would be equally hurtful was it too violent, by making it reftlefs and weakening it; fhould a ftrong evacuation come on, the child would be quite exhaufted, and probably by this means get convultions and die. In the chapter on diarrhœas we may fee what degree of loofenefs is too violent, and the applicable remedies propofed.

From the above observations it may easily be understood,

1. What children breed their teeth early and with eafe.

2. Which on the contrary breed their teeth late and with pain.

3. How a child may fuffer great pain, and alfo die, by dentition, because its father had contracted some distemper, or its mother during her pregnancy has had much forrow, violent passions, used bad diet, or because the nurse's milk has been spoiled.

4. How neceffary it is to accuftom children early to have their gums rubbed.

5. Of what importance it is to know and diffinguish the difeases of children, and that such a science is not within the reach of a midwife's or nurse's capacity.

6. That emollients only are ferviceable when the gums are tender and inflamed.

7. That the brains of a hare, or the blood from the comb of a black cock, has no preference to other foftening remedies; as alfo that a wolf's tooth is not preferable to either polifhed chryftal, or any other hard fubftance.

8. On what occasion the gums ought to be cut down; because in the first period, it would be quite absurd to advise this operation; but in the latter it may be useful when nothing else will relieve.

9. That reachings and gentle diarrhœas at this time ought not to be ftopped.

10. That as foon as the child has got its first twenty teeth, we ought no longer to suffect dentition as the cause of any illness; as the others do not make their appearance before they arrive at the age of seven years.

CHAP.

### AND THEIR REMEDIES.

# CHAP. IX.

# Of the Aphtæ or Thrush.

WHEN a child gets pimples or bladders in its mouth, which foor its mouth, which foon grow ulcerated, or with crusts on them, it has the difease we call the thrush. This is attended with many bad fymptoms, and often endangers the child's life; for befides that children shriek day and night on account of the pain, they are unable to fuck, and confequently fuffer by both hunger and thirst; if at this time they fuck, the nurfe's nipples commonly will be excoriated and fore: if the thrush extends to the throat, they have a difficulty of fwallowing; if it defcends to the ftomach, they will have many reachings and hiccough; and if it extends still farther down in the bowels, the chyle will be prevented from entering the lacteal veffels, and the blood is carried off by a diarrhœa: if this continues long the child must die for want of nourishment.

The thrush is commonly of a white, transparent, or yellowish colour; the blacker it is, the greater is the danger, as all the black spots are mortifications. The deeper and nearer the pimples are to each other, the worse the disease is. When the bladders or ulcers disappear, and soon after return again in greater number, we judge it likewise very dangerous.

The thrush also differs with respect to the part affected.

1. That which appears first upon the lips, gums, tongue, infide of the cheeks, palate, uvula and tonfils, is the easiest of cure.

2. It is very difficult when it descends to the fauces, ftomach, and intestines.

3. It is still more dangerous if it has reached the aspera arteria and the lungs.

4. But the most dangerous of all is that which beginning in the stomach and bowels, ascends to the throat, and appears in the fauces as a membrane of lard. When

When the eschars or crusts at last fall off, it occafions to the children much fpitting, mixed with blood; but when those on the intestines fall off, it produces great fenfibility, and often loofenefs or dyfentery, the excrements being tinged with blood. Thefe four kinds are eafily diftinguishable from each other. The first can be seen; the second may partly be seen, and partly judged of, as the child then has a hiccough, and vomits, especially when it fucks, or it has a diarrhœa, the milk then being mixed with the excrements. When the child has the third kind, it is hoarfe, coughs a good deal, the found being as it were through a metal tube. We judge of the fourth kind, if the child has been affected for feveral days with a ftrong fever, accompanied with great evacuation, is very reftlefs and uneafy, has a hiccough, and the tongue of a fiery red, with an inability of retaining what it fucks.

Those children are most subject to aphtæ, who fuck old milk, or too thick, or too acrid; or by having their mouths unclean : those also who fall to fleep on fucking, as generally then fome milk being left in the mouth, which grows acid and acrid : as alfo those who having been affected with fevers, accompanied with loofenefs. But the thrush generally appears in the time of dentition. The thrush in the mouth is the most common kind, and may generally be prevented by the nurse taking care to keep the child's mouth clean, which fhould be examined every The best thing to effect this is, with a few day. fage leaves well washed, and boiled in water alone, or mixed with a little white claret and clarified honey, and afterwards filtrated. A piece of linnen may. be dipped into this and wrapped round the finger, fo that the child's mouth may be dabbed all over gently, efpecially where any white fpot is to be feen.

But when this has been omitted, and the child has already got the thrush, we must then give the nurse, I. Some of the above-mentioned powder for nurses four or five times a-day, and order her to drink more than customary: 2. Prepare a juice of rob. diamor. dianuc. and honey of roses, half a dram each, to

to which add as many drops of *piritus vitrioli*, as are fufficient to give it a flightly fourish tafte. With this juice we dabb those places five or fix times a-day where the thrush appears, and a little after each time of touching them, before the child is permitted to fuck, its mouth ought to be washed with a decoction of fage, as before-mentioned; or with a folution of a few grains of white vitriol in warm water used in the fame manner. I am fully convinced the thrush may be cured in a few days time, if the above prefcriptions are rightly followed. If the gripes accompany this diforder, they may be relieved by the remedies recommended for them : but above all, magnefia alba, either with or without a little rhubarb; because if any acidity or flime is in the flomach and inteflines, it ought to be immediately corrected and carried off.

When we find the thrush becomes very painful by the violent shrieking of the child, we give the nurse a little fyrup of white poppies (fyr. è mecon. Ph. Lond.) once or twice a-day. When the fuckles the child, after her having taken this, it will find immediate relief, provided her breafts were empty when the took it. The dose is then only two drachms; but if her breafts are full when fhe is going to take this remedy, we may give her three or four drachms at once: or fhould we rather chuse to administer any remedy to the child itself, we may fafely give it once or twice a day, one or two drops, according to its age, of Dr. Jones's panacea. Dr. Riverius gave a whole grain of laudanum with fuccefs to his own child. The worthy Mr. Boyle's remedy for the thrush, is from experience found efficacious. The composition of it is as follows : Take two ounces of the juice expreffed from sempervivum majus, mixed with an equal quantity of honey; after boiling it, add to it as much alum as will give it a flightly auftere tafte. Touch the aphtæ every hour with this. Some make use of the excrements of hens diffolved in white claret, (vin. alb. Gallic.) and filtred, and this is alfo a very good remedy, if used as the former one. When the eschars have fallen off, and excoriations left in the mouth, they should be touched with the mucilage of quince quince seeds alone, or mixed with an equal portion of syrupus sempervivi majoris.

The thrush being internal, defcending to the stomach and inteffines, we give the child as often as poffible a tea-spoonful of a juice expressed from turneps baked, and mixed with an equal portion of mel rofarum; or mix a decoction of carrots with a little mel rofarum, and use it as the former. We may prepare another remedy from half an ounce of flax-feeds beat, and boiled with a pint of water, to nearly the confistence of a fyrup; strain it, and add thereto two ounces" of mel rofarum, and give it in the fame manner as the others. The nurse ought all this time to use the before-mentioned powder, and drink as before observed, that her milk may be diluted. When the scabs or crusts begin to fall off, it is then necessary to give the child a gentle laxative, which ftrengthens Syrup of rhubarb is the best remedy the inteffines. for this purpose, given either alone or mixed with a few grains of pure rhubarb in powder. The fafeft way of giving it, is by fmall quantities every three hours, until it operates. This precaution is very neceffary, becaufe, as we have before obferved, when the crusts fall off, the bowels are very fensible, so that a fmall dofe operates more at that than any other time. Should the child now have the least fign of a dyfentery, we must give it to drink freely of emulsio Arabica, (emulfion of gum Arabic) or a foup boiled of millet, water, and milk.

# CHAP. X.

# On Convulsions, and Epilepsia Infantilis.

HE nerves of children are very fenfible and irritable; they are more numerous in proportion to their bodies, than those of a grown person, and as they have many juices or fluids, their nerves are so much the more softened. They are also covered with very thin membranes, which makes their sensition fo much the greater. For this reason children are subject to startings, and these, at what time of life so ever they happen, are called convulsions. But when the whole body is thus affected, and the sace at the fame time appears bluish, it is then called an epileps. This difease is very nearly a-kin to the true or genuine epileps, and therefore has acquired the name of *epilepsia infantilis* by physicians, but Hippocrates called it *eclampsia*.

This difease appears to be very dangerous. It is by no means fo eafily cured as prevented; therefore it is of importance to be attentive when a child is going to be affected with it. We have great reason to apprehend its coming, if the child fmiles in its fleep, and more efpecially if it does fo when awake. These figns however are of little consequence, if unattended with others. Our apprehenfions of an imminent epilepsy are much better founded, if the child has some obstipations, or fever, or gripes, or a difficulty of making water and of teething, or if its nurfe has been frightened, or has used external remedies against the fcab, or when we know that it has worms. When the child afterwards begins to diffort it eyes, and turn them towards its nofe or upwards; and grows bluifh in the face, the difease is then on the point of appearing. The body either will be convulfed at once, or all its limbs fucceffively, the jaws are locked, and its mouth full of flime. This remains for a longer or fhorter time, till the child falls into a profound fleep; it awakes at length, and feems to be tolerably well.

# DISEASES OF CHILDREN,

72

If the cause is not removed in this interval, the fit will generally return the next and third day, and at the fame hour. The difease then affords a truce for fome time, but may return as foon as the fame or any other cause affects and irritates the nerves. At all times a child may not get off fo eafily, but even lose its life. The paroxylm or fit of an epileply confifts of two periods, the first containing the convulsions, and the fecond their confequences, which are a rattling noife in the breaft, and a profound fleep. It is under the former of these that they die; and as they lie in a state of an apoplectic fit, they are faid to die of an apoplexy, which in fome measure is true. We find in the news-papers many accounts of children, faid to have died of apoplexies, tho' their true caufe has been the epilepfy.

Many things may caufe this difeafe; therefore in the cure of it, we ought to know what is the prefent caufe. In general it is not the epilepfy alone which we have to cure, but in fome certain children it is produced by a particular caufe. I fhall therefore enumerate all the caufes, the method of difcovering them, and the remedies againft each kind.

1. Meconium will caufe an epilepfy, if not fufficiently carried off, by growing acrid in the body, and by irritating the inteftines : for this reafon then it is very neceffary that a new-born child has, for the first days, three or four stools a day. From what has been faid, we may eafily know when the difease arises from this caufe, and it may be removed without difficulty by a clyster prepared of fix spoonfuls of tepid milk, four of oil, and a little sugar beat, and may easier be prevented by the electuary of manna, as already mentioned p. 14.

It also happens, that older children are sometimes, very much obstipated : their excrements then grow hard, or acquire some acrimony, either of which by preffure or irritation will cause an epilepsy. We then enquire of those who have the care of the child, whether it has been costive at all; we seel on its belly to find whether it is swelled, or if there is any hardness, and in that case a clyster, as already mentioned, must be immediately injected : or we may give

give it the electuary of manna, or a little fyrup of rhubarb, with an equal quantity of cold expressed oil of almonds, or instead of that good olive-oil and a little sugar: of this we may give a tea-spoonful or two, every three hours until we judge it will operate, by hearing a noife it caufes in the lower part of the The rhubarb strengthens the bowels, and abdomen. enables them to prefs out the excrements; thefe are loofened by the fugar and the fyrup, and fmoothed and made flippery by the oil. It is upon this account phyficians pretend to relieve children subject to obstipations, by giving them morning and evening a little oil of olives for fome time. I believe it is very ferviceable to procure an instantaneous relief; but cannot help thinking that if used for any time, it must injure the ftomach, lessen the peristaltic motion of the inteffines, and confequently lay a foundation for coftivenefs.

2. Gripes are the most common cause of the epilepsy in children: by sucking too much they will be affected with gripes \*, or by sucking of a corrupted milk, or from their stomach and intestines being too weak. I have myself clearly found, that a weak child may get the gripes without the least fault of the nurse, as the following instance plainly stomes. Two children being suckled by the same nurse, each had no more or less than what was sufficient. The oldest thrived always very well, but the weaker had continually gripes, with green excrements, and with a general indisposition. Though it afterwards got its own nurse, both this nurse and the child were obliged to

\* A child will fuck too much, if the nurfe has that idle cuftom of always quieting it, by giving it the breaft : its ftomach thus overloaded, the milk grows acid, and coagulates : it alfo gets the gripes, if rocked foon after being fuckled, as the milk then curdles in the ftomach as when fhaken in a bottle : for this reafon a child ought never to be put into a cradle foon after being fuckled ; but fhould be put upon the nurfe's knee, its belly and back gently rubbed all over, till it difcharges fome wind. The fleep it takes then, will always be found.

ule

#### DISEASES OF CHILDREN,

34

use proper remedies. It was kept alive, but did not enjoy any settled health, until by degrees it had gained confiderable strength.

The figns of a child's having the gripes, may be feen in the chapter on that fubject.

In an epilepfy arifing from this caufe, we ought to inject a clyfter during the fit; for as the child is at this time unable to fwallow any thing, it is ufelefs to pour any thing into its mouth. As foon as the fit is over, we give the nurfe fome of the before-mentioned powder for nurfes, fee p. 19. to take feveral days together, as much as will lay on a knife point : this is to be taken four or five times a day, and the child muft be treated as above prefcribed in the Chapter on Gripes.

They must both continue the use of the fame remedies until the child's excrements have acquired their natural colour; in the mean time, to prevent any returns of the fame disease, we must take care, that the nurse observes a regular diet, and such a one as has already been mentioned in the Chapter on Nurses.

Dr. Joh. G. Zimmerman in the Acta Societatis Zyrich. Vol. II. p. 396, gives us an inftance of a child, who during the first months of its life, had frequent attacks of violent convulsions or epilepsies, which went off entirely, as soon as ever the child was taken away from its feeding on meal-pap.

3. Passions of the nurse, are another cause of this difease; for the child fucking her foon after the has been by any means frightened, it will commonly be affected with convulsions; but among all the passions of the nurse, none has such violent effects, and dreadful confequences, as when fhe is exafperated. This fhe knows commonly how to difguife, better than any other emotion of the mind; but yet we have reason to fuspect something of this kind, if her eyes are fiery, the colour of her face changing now and then from a pale to a red. Our apprehensions are yet better confirmed, if the child, being a little before healthy, becomes of a fudden yellowish in the face, or if immediately after having fucked, it is attacked with a fudden vomiting, shortly after begins to moan, is restlefs, and

and now and then has flartings, which are foon changed into an epilepfy. We may eafily know, that all thefe fymptoms do not proceed from the child's only having fucked too much, as in that cafe it finds relief by puking; but to make ourfelves fure of this, we fhould enquire into it, from the other domeftics. The greater number of children would certainly lofe their lives by the nurfes being exafperated, if this paffion was not in general followed by quite a contrary one: this is the fear, I mean, and her apprehenfions of being difcovered, and difmiffed from the fervice of the family. This laft confideration, in a great meafure, composes the emotions of the mind occasioned by the former.

We have already taken notice in the first chapter, how to prevent the child's being endangered, when the nurse has been exasperated, frightened, or affected by any other paffion; but fhould the child already have got convultions produced by fuch an effect, we must immediately inject a clyfter. The fit being over, we ought to take care, that the child's ftools are both in proper quantities and regular; they may be promoted in the manner above observed, and the nurse must also use those remedies recommended for that purpose. If notwithstanding this, the child on the following night is reftless, has at times startings, we ought to give it a little syrupus è Meconio, ph. Lond. (or syrup of white poppies) in the manner recommended at page 24. and the next day inject another clyfter, just two hours before the time of its being attacked the day before by the epilepfy\*. The mother or nurfe ought alfo carefully to avoid fuckling the child immediately after having received any unexpected joy or for-

\* In a family were twins, and each had his own nurfe; they fell out with each other. The weaker child being fuckled by its nurfe foon after, it inftantly became weak to fuch a degree, that it was unable to move hand or foot: it grew pale, and unable to fhriek. Rhenifh wine being warmed as faft as poffible, napkins were dipped therein; and wrapped round the child. It recovered again, and another nurfe was procured for it afterwards.

row.

row. We have inftances of this kind, where children have been feized with the epilepfy, and been carried off by it.

Children will alfo get this difeafe by fucking a nurfe at the time her menfes are upon her : the obfervations of phyficians are filled with fuch inftances. It may either be owing to the great pains and gripes thefe difcharges are attended with, or to the woman's mind being more fenfibly affected at this, than at any other time. Which ever of thefe are the caufe, the child ought by no means to fuck during that time; and if the epilepfy has already attacked the child, we firft inject a clyfter as before ordered, and after it has operated a little, fyrupus è Meconio, ph. Lond. or fyrup of white poppies, mult be given to it.

4. Difficult dentition, and the children at that time not having loofe stools, is the fourth cause of the epilepfy; but the convulfive motions are generally more confined to the face at that time. We may learn how to prevent and cure this by referring to the Chapter on Teething. During the fit we can do nothing more than administer a clyster; but if the disease is in its infant-state, and attended but with little fever, the child crying continually, has ftartings during its fleep, or is very reftlefs, then we may boldly give to it one or two drops of Dr. Jones's panacea, or of Dr. Sydenham's laudanum liquidum. This may be taken in any convenient liquid ready at hand: it may also be repeated once or twice, if judged neceffary, and the dofe carefully afcertained by the then attending phyfician: by these means we may be fure of preventing convulfions, and their returns too; but if the child should have a fever, it ought either to be bled, or leeches applied upon its temples. See the Chapter on Dentition.

5. Scabs repelled, if they caufe an epilepfy, may eafily be known; for fhould the child have had any eruptions, and by being exposed to the cold, or the fcab anointed, it has thereby been more or less repelled, it is pretty certain the difease arises from thence. During the fit, all we can do, is to inject a clyster, and when it is over, the nurse ought to take a little flower

# AND THEIR REMEDIES.

flower of fulphur, the quantity of half a drachm, morning and night, in a little warm milk; or we give her every two or three hours a table-fpoonful of the following camphorated mixture.

> R. Camphoræ 3 ß. Sacc. Alb.

Mucilag. g. Arabic. ana zj. tritis in mortario vitreo & adde Aq. Flor. Ulmariæ, (or meadow fweet) Zvj. Syr. Baccis Norlandicis, g. f. M. Dr. ut fupra.

We fhould befides, if in our power, caufe the child to fwallow a grain or two of mufk, previoufly well rubbed with ten grains of fugar, which fhould be repeated once or twice a day \*; if we can procure the fcabs to appear again, the child will be faved for this time. What relates farther, either towards the cure or prevention of this difeafe, will be fpoken of in a particular chapter towards the conclusion of this work.

6. The fmall-pox, meafles, and fcarlet fever, are fometimes accompanied with an epilepfy juft before the eruption appears. Happily it is feldom dangerous, but on the contrary is an indication of the fmallpox being of a benign or favourable kind : for this reafon we give nothing for it, except what we intended for the difeafes themfelves, and which will be treated of in their proper places. It is fufficient, in order to diftinguifh this fpecies, to know that the child has not had the fmall-pox before, and that the contagion, by being in the neighbourhood, may have been brought into the family by fome one or other; and that the child has for three or four days paft been affected with a fever, accompanied with the figns which exanthematic fevers commonly have. See fur-

\* If this does not prove effectual enough, I find phyficians recommend a very nafty cure : it is to put the child on a fhirt, which a fcabby perfon has previoufly wore; this occafions by its irritation a fresh fcab, and makes the former one re-appear. Mr. Deidier cured, by this means, a hydrops occafioned by fcabs repelled. See Sauvages, not. iii, ii. p. 431.

ther

ther on this, under the proper heads. We may make ourfelves pretty eafy in this cafe, as we know the epilepfy preceding it, is a good fign. Notwithftanding this, I have heard of children dying of convultions; and that even after the exanthematic fpots had made their appearance.

7. Worms commonly caufe the epilepfy by violent fits, and frequent returns. Happily this fort, as I imagine, rarely attacks children, whilst they live merely by fucking: for as yet, I have never observed any figns of worms in them, until they have had recourfe to other kind of food. This species is one of the most difficult to know, for I have frequently feen children of a ftrong conftitution to void worms, with fuch a composure of countenance, that it is hardly poffible to judge of it by looking in its face. We have pretty good reasons to suspect their being affected with worms, if it often fcratches its noftrils, has ftartings whilft afleep, and fwallows as it were, whilft in that ftate; its breath of a bad and fourish fmell; its mouth filled with water upon awaking in the morning, and its face frequently changing colour; if, befides this, the child has a difgust for food, sometimes a violent appetite, and fometimes to that degree, that it feems almost fainting, if it does not foon receive its nourifhment; if its ftomach is hard, and fwells a little before the usual time of its eating; if it grows fick of fugar, or other fweet meats, is well one moment, and complaining the next of its ftomach, and of the gripes round about the navel; if it has a few reachings, fometimes going away, and appearing at unexpected times, and without any manifest cause: but our apprehensions are wholly confirmed, if it has a little before voided worms. I have feen feveral children affected with convulsions from this cause, and always during the fit found the navel prominent.

However violent the attacks of this kind are, they may eafily be removed by injecting a clyfter of tepid milk, to which a little falt muft be added in cafe the child is coftive, otherwife not. The clyfter ought not to contain any oil, honey, or fugar, becaufe as worms are faid to avoid thefe remedies, they remove further up in the inteffines. In this manner we may relieve

relieve convulfions, but they may return again, as long as the worms are kept alive and unexpelled, as their biting or fucking occafions another fit. We ought by no. means long to neglect the means of expelling worms, as they increase in fize and proportion according to the time they have been undifturbed. This subject will be more minutely inquired into in another place, and therefore let it fuffice here only to observe, that young children ought every day to eat honey, and fresh carrots, when ever they can be procured. Children more advanced in years, ought to drink fome mineral waters, but more efpecially bitter water (the aq. Zeltherana), and tho' its tafte is very difagreeable, we may entice it to drink it, if in each glass fomething is put, which they are fond of: for inftance, a piece of fugar, which by finking to the bottom, is a temptation for them to drink it, that they may eat it as foon they have drank out the glass. Those small white worms (ascarides), which live in the lower part of the inteffines, are the easiest to get rid off, by injecting a clyster of warm mineral water, to which we may add a little falt, as it otherwife would not purge.

8. Cold fits of a fever accompanying this difeafe, I firmly believe to occasion fometimes the epilepfy : for the convultions returned with each paroxyim of the fever, and went off entirely, as foon as the intermittent fever was cured. A clyster immediately stopped the fit; but in these cases, as soon as the child was a little recovered from the feverish fit, I have given an emetic to it, with every possible precaution, and according to the method laid down at the end of the Chapter on Chin-cough. After the operation of this remedy, I have given the juffly famous Jefuits bark.

9. Gravel, or the stone, is fometimes also found to affect children, and cause an epilepsy: providentially the gravel in children is a very rare difeafe in Sweden; and as they cannot, at fo young an age, well point out their distresses, it is very difficult to discover whether the gravel is the caufe or not. We may judge it fo, if the child cries whenever it makes water, it being fometimes

39.

fometimes of a fudden ftopt, or much voided at once, the child moaning all the time. If we find that its parents have had the *arthritis*, gout or gravel, our fuppolition in a great measure is confirmed; and still more fo, if by introducing the finger into the *rectum*, and carrying it forwards to the bladder, any thing hard and moveable is felt; but no kind of doubt remains if a stone is felt by the catheter.

During the fit the child ought to be bled, and feveral clyfters fhould be administered : at first they may be prepared of three or four spoonfuls of warm milk, and an equal quantity of oil, with a little fugar, but afterwards of oil alone. We may make a poultice of flax-feeds beat, mixed with a little faffron and milk; with this we fill two bladders half up, and apply the one above, the other below the place affected; taking care they are conftantly kept of a moderate warmth. Luke-warm baths are also of great efficacy. We may give internally a palliating milk, prepared from an infusion of mallow flowers, (infufum flor. malvæ) oil of almonds, the yolk of eggs, and a little fyrup of white poppies, (Syr. é Mecon. Ph. Lond.): the proportion is this; half a pint of the mallow infusion, an ounce of cold expressed oil of almonds, half the yolk of an egg, and two drachms of the above-mentioned fyrup; shake them well together in a phial, and give it to the child to drink by degrees until it finds relief.

10. Theriaca, Diascordium, Philonium, and other remedies of that kind, in which are contained opium, have already been mentioned as prejudicial when improperly given. Phyficians have enumerated many fad instances of the death of children, or at least the epilepfy being brought on by the nurfe's giving them these remedies. It is our business then to prevent, if poffible, the nurfe's or other ignorant people ever being informed of the name of opiates; the most difficult thing is to find out when the child has taken any thing of this kind, as it is generally done fecretly : for the truth of this we must enquire strictly, from the other people of the house; and if nothing certain can be inferred from thence, we must then judge from the 5

the effects opium has upon the human body. The fymptoms arising from having taken it, are, a quick pulfe, heat, fhort and difficult respiration, sweats smelling not unlike opium, coffiveness, and frequent urining; the face appears red and puffed up, and the iris dilated; the blood flows towards the head, and occafions a giddinefs, with a peculiar composure of the mind, either asleep or awake, or a great propensity to flumber. If we find out that any opiate is the caule, we immediately give the child fome milk-warm water, to which is added a little butter, or oil, afterwards irritating the fauces with our finger or a feather, in order to excite a vomiting; if this does not fucceed, we then inject a clyster, with a little falt, rub its feet with a flesh brush, and apply to the soles of them a stimulating cataplasm until the skin becomes red. Its head must be fomented with warm vinegar, and a sponge dipped in ftrong vinegar put to its nofe. Could the child be bled, it would be of great fervice, but of much greater if leeches were applied to its temples. I shall, not mention acids taken internally, although they are the most powerful in correcting the bad effects of opium : as in general we do not think these remedies fo applicable to tender children, unlefs those before prefcribed fhould prove infufficient. In the fame manner we proceed in convultions ariting from having eat any poifonous plant; as for inftance the root of henbane (Radix Hyofcyami) or the berries of the deadly nightshade, (Atropa belladonna Linn.) or any thing fimilar, which through imprudence or ignorance we fometimes lay hold of. The best antidote and cure is, first give them good vinegar, and afterwards an emetic.

The epilepfy occafioned by venereal acrimony, will be mentioned in another part of this work. Want of food will caufe convultions; for inftance, the nurfe's milk being dried up, and her concealing it; this may eafily be cured by procuring another nurfe. When this difeafe arifes from ftrong and violent evacuations, they ought to be ftopped, as may be feen in the chapter on vomiting and diarrhœa.

There are inftances upon record by phyficians, of convultions or the epilepfy in children, occasioned by their their fwallowing fome blood, at the operation of cutting the tongue-ftring: in this cafe we eafe them either by a gentle emetic, or a little fyrup of rhubarb, and a clyfter.

Tickling children is very dangerous : they may from that get convultions, and even lofe their lives; as may be feen in Dr. Van Swieten's Comm. iii. p. 402, and Dr. Robinfon on the fpleen, p. 148.

We observe in general,

42

1. That the second, third, fourth and seventh species are the most common.

2. That the child, if robuft, ought to be bled, and is fomething more than a year old, and not weakened by any other difeafe; notwithftanding, the applying of leeches is preferable to bleeding.

3. That during the fit, fomething ought to be introduced into the mouth, fo as to prevent the tongue being hurt.

4. That clyfters are not only the beft, but the moft ufeful remedies during the fit, as they cannot fwallow any thing in the heighth of each paroxyfm; for whatever we attempt to give them internally, generally runs out of the mouth again. Warm baths are generally ferviceable, as they calm the convulfions fo much, as they are able to take fomething internally.

5. Wrapping them up during the fit in warm rhenish wine, is of an incomparable effect, as I have frequently experienced. Poorer people may, in lieu of this, apply a piece of linnen soaked in warm brandy to the child's stomach.

6. That the epilepfy is not to be prevented by hanging round the child's neck the officinal root of vervain, (*Radix Vervena*) as I have known this preventative used by many children, who notwithstanding have frequently had convulsions.

Laftly, we may observe, to the great comfort and fatisfaction of the parents of those children subject to convulsions, or the *epilepsia infantilis*, that they need not be apprehensive of its changing into the true epilepsy; for it generally disappears by degrees, as they grow older and acquire more strength: this is owing to the sensibility of the nerves, (which has been before

## AND THEIR REMEDIES.

before observed is the cause of convulsions in children) being by that time diminished \*. In the mean time the child's parents should minute down every thing that happens to the child before, during, and after each fit; whether or not it ended with a reaching or loofenefs. Alfo if any thing is observed in the child's diet, nurfing, &c. which occafions the fitsto be more or lefs violent, or more or lefs frequent : this will be of infinite fervice in confulting with a phyfician, who by fuch a minute account will get a greater knowledge of the nature of the difeafe, and confequently be better able to cure it. It will also be of use to the parents, as from these observations they will not only learn the preventatives, as well as the means of cure : for instance, if they observe the fits returning every fortnight, and end each time with a loofenefs or a vomiting, they may eafily perceive that in the first. case the child ought to take, for three or four days running, a gentle laxative, beginning about the tenth or eleventh day after the last fit. In the fecond cafe, as the paroxyfm ended with reachings, an emetic ought to be given in the fame manner as above ordered, fo as to avoid all flimes before the time the convultions are expected to return. When the epilepfy returns every fourth week, we judge it to be then owing to the nurfe having her menfes; and if upon enquiry we find it fo, we must not permit her to fuckle the child at that time, as fhe then cannot help being exasperated even by any triffing matter, and

\* By this we find that as we advance 'in years, we lofe our fubtler fmell, tafte, hearing, and fight; and that the nerves in the bladder and inteftines, alfo lofe their irritability by degrees, and that they do not fo eafily excite towards the neceffary evacuations as in the younger years. In old people they are proportionably lefs, as they do not increafe in this part as in the other parts of the body; they alfo lofe by degrees their foftnefs, and confequently in childhood are the most irritable. How can they then be faid to have any tension? Dr. Hillary tells us that the children in the Isle of Barbadoes are fo fensible, that they get convulsions by even the least noise. See V. Haller's Elem. Physical. iv. 203. 294.

often

# 44 DISEASES OF CHILDREN,

often to the imminent danger of the child. When the child has flinking breath a day or two before each fit, we then fufpect it to arife from worms or a weak flomach, and as fuch, conform both to the cure and diet thereof. The flowers of *Cardamine pratenfis*, half. a dram for a dofe, are recommended by Mr. *Baker*, in Medical Transactions, by the college of physicians, vol. i.

With regard to the *fraxinella*, time will convince us of its efficacy in the cure of the true epilepfy. It is a remedy much approved of, by that worthy friend of mankind, Mr. Stoerk:

# CHAP. XI.

# On the Loofeness, or Diarrhœa of Children.

CTOOLS thin and loofe, and more frequent than I usual, are called a diarrhœa. By the peristaltic motion of the inteffines the ftools are promoted; by the natural mucus filtrated from the blood by their glands the bowels are kept fmooth; by means of that vapour, or steems arising from the pores of the vafa exhalantia in the æsophagus, stomach and intestines, the excrements are prevented from becoming hard. This vapour is again abforbed, and re-enters the blood by the vafa lymphatica, or bibula. The faliva or fpittle, which is fwallowed, promotes also the fame. The gall is diluted by that humour, which the fweetbread (pancreas) feparates from the blood, and is continually flowing to the largest of the intestina tenuia; both these promote the digeftions and ftools; but it is chiefly owing to the gall, that the bowels are excited to their peristaltic motion: for this reason it is, we find it fo difficult in the yellow fever (icterus), to procure ftools : also when the gall-bladder is pierced : also when the gall is much weakened by the great abufe of acid food and drink; as for instance, in the acid colic, called colique de Poitou vegetale. A diarrhœa may arife from whatever occasions a greater quantity to remain in the bowels than ufual, or by any thing cauling

caufing the above-mentioned humours to be difcharged in too great a plenty; or from any thing preventing the vafa bibula from abforbing those liquids, and by whatever increases the peristaltic motion. By eating and drinking in too great quantities, the ftomach and inteftines are unable to digeft the food, and from thence will arife indigestions and crudities, which by their acidity, irritate in part, and increase the motus peristalticus, and in part occasion a greater flux of humours, just as we fee a grain of fand irritates the eye, and causes the tears to flow from thence. The fame happens also when the gall is either too acrid, or is prefied into the intellines in too great quantities : for instance, when we are exasperated this happens; also by the blood being acrimonious, as the liquids feparated from it into the bowels, are of a fimilar quality, and their irritation occasions a greater flux of humours, and increases the peristaltic motion : for this reafon a diarrhœa is always preceded by rumblings of wind, which is an indication of an increase of the peristaltic motion of the bowels. The fame effect may arife from new beer; it is upon this principle that pills of yest are purgative; change of water has the fame effect. especially amongst those who use it for their common drink. Eating too freely of melons, has the fame effect as water-melons, rafpberries, and other fruits, or by fucking the inner bark of the firr in fpring \*; from the insensible perspiration being obstructed it is frequently thrown upon the inteffines, and confequently increases there the quantity of fluids : therefore those fubject to costiveness, may promote their stools by rifing early, as the perfpiration is by this fomething diminished. The fame, though in a more violent degree, is occasioned from the stronger purges, or from any purulent matter, which by a metastafis is discharged from any internal or external ulcer; being fometimes first abforbed by the blood, rarely to the advantage of the patient, as it generally vitiates

\* In countries where firrs abound, the people make very frequent use of the inner bark, which contains a very fweet and palatable juice. S.

this

46

this fluid, and melts it as it were, fo that the body, unable to retain it, carries it off, either by a nocturnal fweat, or an incurable flux. The patient thus exhaufted, dies like a lamp wanting oil. The humours are alfo increafed in the inteffines at their glands, and their pores are quite relaxed and corroded at their orifices; alfo if the vafa bibula lofe their power of abforption, which is the cafe when their orifices are too relaxed, or flut up by flime, crufts of the thrufh, fmall-pox, or meafles; or alfo fhould there be any obftruction in the liver, or mefenteric glands. They may even flut up by any acrimony in the guts, as what flows from thence by irritating and increafing the vafa exhalantia, or perfpiring vefiels, occafions a contraction of the abforbent vefiels.

The urine in a diarrhœa, is in much lefs quantity than before, and is alfo redder than ufual; it is therefore a good fign, when it is difcharged in a greater quantity, and its colour is clear. This fhews a lefs flux towards the inteftines, and a more equal division of the fluids, in order that they may alfo dilute the urine. By this we learn the reason of our being obftipated by drinking mineral water, when it is carried off too foon.

By the fame reafon we judge of a diarrhœa's going off, when the patient falls into a profuse moifture, or sweat: therefore those, who use hard labour, sweat much, or frequently urine much, are generally subject to costivenes: for this reason did Dr. Riverius cure himself of his diarrhœa, by means of the warm bath.

Reachings in a diarrhœa occafion frequently fome good change, partly by diminishing the matter occafioning the flux, partly by causing a motus peristalticus inversus, and partly by shaking fomething loose, which was before adherent, and irritating in some part of the intestines.

A diarrhœa in a confumption fhews that the patient approaches to his end; if this evacuation does not relieve other internal or external ulcers, it will then hasten his death. The same is to be observed of a diarrhœa in a dropfy; purging medicines are therefore prejudicial in that kind of hydrops arising from a weakened

weakened or corrupted stomach and intestines, or from obstructed perspiration. In this case they would still weaken the bowels, and hurt the digeftion. They also obstruct perspiration, and dispose the body in the fame proportion to abforb the moisture of the air by the absorbent pores of the skin. In wounds of the head they occafion great mifchief, likewife to women in child-bed, and during their pregnancy. In ardent fevers, unless when the stomach and bowels are filled with crudities, they are prejudicial.

As long as a diarrhœa is unattended with a fever, does not diminish the appetite or strength, the gripes are not violent, and the patient upon going to ftool finds himfelf easier, it ought not to be stopped : by fuch an evacuation, we are freed from a quantity of crudities or stagnant humours in other parts of the body, which might otherwife have occafioned more dangerous diseases.

We ought more especially to be cautious in not ftopping a diarrhœa in those affected with pains of the head, or on either fide of it, (migrain); with colds or rheumatic pains of the neck, eyes or ears; nor in those who have the anasarca, as a loosenes is then often beneficial, as it is also when it appears in dentition.

A diarrhœa, when carried too far, ought to be ftopped, otherwise the intestines would lose their digestive faculty, by being too much foftened and relaxed : those fluids requisite for digestion are carried off, by which the blood not being diluted with a new and fuitable milky juice (chylus), grows acrid, and unfit for the support of the body, which then pines away, its strength diminishes, the legs and feet swell; and either a confumption or a dropfy at last closes the fcene.

It becomes too inveterate, when joined with fever, difgust for food, violent gripes, a weakness increasing after each stool, and the excrements being of an unnatural colour and fmell, and no eafe to be found in those difeases the patient had previous to the diarrhea, which was expected would be of fervice : befides if we know that the patient has had a good ftomach, has not overloaded it, has taken much exercife, as other children, we then ought to ftop it early; otherwife

48

otherwife it would degenerate into an habitual diarrhœa. We ought to avoid every thing that might occafion a diarrhœa in the months of July and August, when the days are hot, and nights cold, as it might easily degenerate into a bloody flux. From what has already been observed above, we find there are many kinds of diarrhœas; but I shall enumerate those only to which children chiefly are subject.

### First Species.

The younger we are, the eafier are ftools procured, and alfo fleep; but the more we advance in years, the more coffive and reftlefs we grow: for this reafon a tender child at the breaft, fucking freely, and having three or four ftools every day, ought not to be looked upon as having a diarrhœa.

At fo early an age as this, they are rarely affected with this difease, and whenever it happens, it arises from either the mother or nurse having neglected the child, or from their having a corrupted milk. They neglect it by not adhering to the rules laid down in the Chapter on Nurses: especially if they allow its feet and ftomach to catch cold by hanging wet clothes in the fame room to dry; by the nurfe's fuckling her child too often, or whenever it cries, or by fuckling it in the morning before the has eaten any thing, or by giving it hard food before it has gotten its teeth, or by her feeding too often on falt meat, or much fruit, cucumbers, berries, acid drink, or by her having the gripes, without complaining and being cured of them first; by changing the nurse, and giving the child one whofe milk is younger. What are the requifite qualities for approving a nurfe's milk, may be feen by referring to the above quoted chapter.

Those therefore, who have the management of children, should adjust these matters, and for the future take better care of the child; but if, notwithstanding their cautions, the diarrhœa should continue, we must give the nurse some of the powder ordered in the Chapter upon Gripes, (which see), and rub well the child's stomach with a little balm of nutmegs; or with some of the following composition: Take of

Theriaca

# AND THEIR REMEDIES.

Theriaca, two drachms, Balm of Nutmegs, one drachm, Oil of Cummin, fix drops. Mix them.

Spread this upon a piece of thin leather, and apply it to the child's ftomach. Should it be requifite, we may give a clyfter of milk, with a little white ftarch, once or twice. If this difease is occasioned by the gripes, we must use the remedies against them.

#### Second Species.

If a child eats and drinks in fuch quantities, that the food cannot be digefted, the quantity alone will occafion a diarrhœa, by reafon of its weight and irritation.

Food having been eat, that is bad in refpect to quality and quantity, undergoes the fame change in the ftomach and bowels, as if we were to keep it in any veffel, equally warm and moift with that of the ftomach : that is to fay, it will acquire an acrimonious quality, which would irritate and caufe a diarrhœa. For a further explanation of this fee the Chapter on Coughs, efpecially in coughs of the ftomach, and of vomits, the fourth fpecies, where the figns and different natures of crudities are taken notice of.

This fecond species is the most common, and ought not by any means to be ftopped hastily, as this carries off the cause which produces it, and which by being retained, would occasion more dangerous difeases. Should it not go off spontaneously, but the gripes increase, much rumbling felt, and the patient becomes much weaker, we are then obliged to relieve it by remedies, and as in general it is accompanied with loss of appetite, and a disgust for sood, an emetic would be of great fervice, and should immediately be given.

Should there be no kind of loathing, but gripes and wind only, we then give a little rhubarb, eight or twelve grains in powder, according to the age of the child; or we may give it a little elixir of rhubarb, without fugar, a tea-fpoonful or two; or a little of the rhubarb-tea (fee the Chapter on Vomiting) to the quantity of two tea-cupfuls; fometimes a fingle dofe E proves proves fufficient, and at other times it is requifite to be repeated two or three mornings fucceffively, effecially in those who have lived irregular.

If by the figns mentioned in the Chapter on Vomits, we fhould find out the nature of the crudities, we must then use the remedies recommended for each kind, either feparately or mixed with the rhubarb; for instance, if they arise from acidities, we join to the magnefia alba fome of the powder of oyster-shells, or diffolve fome *fal Tartari* in the elixir of rhubarb : if they are owing to putridics, the patient must drink Tome limonade, or almond milk, &c. their drink ought alfo to be thin rice or millet gruel, which we make into almond milk, by the addition of fome fweet almonds: if the child is very weak, we then give a little white wine whey; or should it at this time be judged neceffary to ftop the diarrhæa, we may infuse in warm whey a piece of cinnamon and some toafted bread, ftrain it, and when cool, give it fome to drink; when the crudities are owing to acidities, weak flefh-broth is by much the beft.

If the diarrhœa notwithftanding continues, it will then be requifite to apply to its ftomach the preparation at page 49. over this we lay a napkin, and a piece of thin board, to preferve the warmth better. We give the child dried bilberries to eat; the richer people may apply the *emplaftr. ftomach. Ph. Londinenfis* upon the ftomach; but if the difeafe does not yield to this, we give it a powder prepared of

#### Red Bolc, ten grains, Gum. Tragacanth. five grains,

after every loofe ftool. This powder may be taken in a liquid prepared of two drachms of gum. Arabic. or gum of cherry-trees, diffolved in a quart of thin foup, rice, or millet gruel; or we diffolve two drachms of wax, ftirring therein as much powdered oyfter-fhells as it will take up, and give it as the former. At bedtime we may give a few grains of theriaca in either a little milk, or weak cinnamon water (aq. cinn. fimpl.): many have been cured by drinking milk, in which a drachm or two of thin flices of wax has been boiled. Others have met with the defired effect, by drinking

drinking chicken broth, wax having been previoufly put into the chicken. Others again have been quite relieved by eating an apple or two with wax therein, and baked over the fire, fo that the wax, has been abforbed into the fubftance of the apple. However, the rhubarb or the emetic ought always to be taken before any of thefe remedies, and they feldom fail of fucceeding.

When the difeafe at laft is ftopped, we endeavour to reftore ftrength to the ftomach and bowels, by the ftomachic elixir, and a proper diet, taking care not to overload the ftomach.

Should the child be attacked with a head-ach, or any other diftemper, as foon as the diarrhœa is ftopped, it gives us fome reafon to fufpect we have rather been too hafty in ftopping it; and that there ftill remains fomething in the inteftines, which ought to have been first carried off. It is then requisite to give the child a little rhubarb again, in any of the forms above-mentioned.

To this kind belongs alfo that violent diarrhœa, which comes on during the ufe of mineral waters, and arifes from having eat too many ftrawberries the night before. It may eafily be relieved by taking a little cinnamon-brandy.

### Third Species.

When the orifices of the perfpiring and abforbent veffels, or those of the intestinal glands, are relaxed to that degree, that the humours are as it were flowing from them into the bowels, and if they are not received there by the abforbent pores, they will occasion a dangerous diarrhœa, which might soon emaciate the patient.

This kind may eafily be diffinguished from any other, by being unattended with pain, or gripes; the excrements having nothing purulent, or any thing unufual in them; there are not any figns of crudities either; those affected with this kind, are weak and pale, with loss of strength.

As it, for the most part, carries off all the humours from the body, the sooner we stop it the E 2 Better; better; it may be done, I. By giving the child dry food, and abstaining from soups, butter, or any thing similar, which would increase the laxity; its drink should be water, in which a little cinnamon, or bitter orange peel, has been boiled, strained off, and cooled. 2. By giving them a tea-spoonful of the chalybeate wine, two or three times a day, in a little cinnamon water, or any other steel tincture; or by a few grains of the Æthiops Martialis. The celebrated Dr. de Haen lays a great encomium upon the powder of an herb, called *lysimachia vulgaris flore purpureo*.

This kind of diarrhœa arifes also in confequence of others being neglected, or fuffered to remain too long; a circumstance very frequent among the poorer people.

It is alfo a confequence of forrow, fudden fright and jealoufy. It is true, that children's forrows are of no long duration, but are foon forgot, unlefs daily renewed by a bad mother, or a teacher. Envy or jealoufy will frequently take place in a child, when it obferves the other children more carefied than itfelf. As long as the caufe remains, the difeafe cannot be removed; but that once taken away, it rarely requires any other remedies, except those abovementioned.

#### Fourth Species.

If children are fuffered to play late in the evenings, exposed to the open air, during the summer seafon, or harvest, when the days are fultry, and the nights chill, they will either catch cold in the head, or breaft: get a diabetes, or will be affected by a diarrhœa, generally accompanied with gripes. The pores of the fkin being a great deal opened in the day time by the heat, are flut up in the night by the cold : by this means the perspirable matter being repelled, goes to the intestines, and occasions a diarrhœa. If they lay down upon the ground to reft, when warm and fweating by exercife, they will get it much fooner. Children have a very thin and sensible skin, therefore they sooner feel the effects of heat and cold, as do all weak people. Robust people, whose skin by means of

#### AND THEIR REMEDIES.

of hard labour, and coarfe linen, is become as thick as leather, are feldom thereby affected.

This fpecies is eafily known from any other, by the circumstances already mentioned; its cause is also taken notice of. With respect to the cure, it is pretty eafy; we ought at first to cleanse the child's ftomach and bowels by an emetic, or a little rhubarb, fhould it be found loaded with crudities, which may be known by the symptoms mentioned in the Chapter on Chin-cough. Afterwards we promote perspiration, by putting the child into a warm bed, giving it an infusion of elder flowers (flores fambuci), and applying to its ftomach three or four fheets of blotting paper, soaked in warm brandy, or rather in camphorated fpirits, previoufly warmed over the fire in a deep pewter plate, and afterwards wrapped up in a thin linen rag. The diarrheea generally ceases as foon as any moisture or sweat is procured; but if notwithftanding it should continue, and the gripes also, it would be best to give a little rhubarb once more, and at bed-time a little theriaca, to which we may add a grain of camphire. This may be taken in a little of the above-mentioned infusions.

### Fifth Species.

There is another kind of diarrhœa, which fometimes affects children, that live upon much fat food, as pork, fat pan-cakes, or bread and butter. Rancid crudities will be generated from thefe, caufing by means of their acrimony a painful loofenefs with gripes. Phyficians term this kind of diarrhœa biliofa; as it alfo arifes from a very acrid gall being in great quantities prefied down into the inteffines, either by violent paffions, or becoming acrid during hot and dry fummers, and in the harveft time, when the perfpiration being retained by any cold, it will occafion either a very violent fever, or a diarrhœa which prevents this fever, and unlefs this evacuation happens they can hardly be cured.

From the above-mentioned circumstances, and also the excrements appearing yellowish, green, &c. we distinguish this species from the others; and notwith-

E 3

#### DISEASES OF CHILDREN,

54

standing it is a very obstinate kind of flux, it frequently prevents and cures pains in the stomach, nauseas, oppressions, reachings, colics, intermittent and bilious fevers.

Therefore this evacuation ought not to be too haftily ftopped, but the rancid crudities, or acrid gall, should be first diluted, so as the diarrhœa may not be too violent; this we procure by giving the child, by degrees, plenty of milk-warm water, or fome whey made with the juice of limons, or barberries, or with vinegar, four bread, or hips (fruits of rofes), buttermilk well strained, almond milk (emulfio Arabica), mallow tea, or millet gruel. In the interim we promote the evacuation with a few cups of the rhubarbtea already mentioned, or by a drink prepared of an ounce of tamarinds boiled in half a pint of water, and ftrained off. Should it not yield to this, we must then ftop it with fix or eight grains of rhubarb toafted, given after every loofe ftool; or by a mixture of half a dram of fuccus cathechu diffolved in half a pint of water; or by fome foup in which we have boiled plantain leaves ('folia plantaginis); or in case the gripes do not ceafe, a few grains of theriaca towards evening.

We ought never to omit reftoring strength to the stomach and bowels, by means of convenient food, the stomachic elixir, globus Martis (boule de Mars), or the chalybeate wine.

#### Sixth Species.

When any one by ignorance has given too firong a purge to a child, it will thereby be affected with terrible gripings, pains in the abdomen, convultions, &c. and even fometimes lofe its life; we fave it, by giving it a quantity of fat foup, warm milk, and oil, cream or fresh butter. It would be imprudent to give any aftringent remedies before the purge is expelled the body, becaufe its retention would corrode and inflame the intestines: for this reason we give a clyster of fimilar remedies, with an intention of lining the bowels as it were, to lubricate them, to edilute, and by that means blunt and weaken the physic. phyfic. When the evacuation begins to decreafe, we may then according to the child's age give a few paregorics: for inflance, a drop or two of *Laudanum liquid. Sydenb.* in a little milk; taking care not to be too bufy in giving this. There are inflances of its proving deadly by retaining the caufe, as are related in the *AEta Edinburg.* tom. iv. n°. vi. where is mentioned a cafe of one, who by ignorance took fix grains of *tart. emeticus*, which produced vomit and diarrhœa; but by taking twenty drops of *Laud. liquid. Sydenb.* in order to ftop them, death was the confequence.

Professor *Cellarius* was more fortunate in his miftake; he took all the purging pills at once for a deafnels, which were to have been taken gradually in the courfe of feveral days: after he had found out his mistake, he afterwards drank a quantity of foup with fuch good effect, that the purge operated but moderately, and his hearing was reftored.

#### Seventh Species.

When a diarrhœa arifes from fcabs, or other eruptions being repelled, it may be cured by the remedies recommended in that Chapter on Cough.

### Eighth Species.

That kind of diarrhœa accompanying the fmall-10, is treated of in its proper chapter.

#### Ninth Species.

That kind arifing from the contagion of the measles, is treated of in the same chapter, as its principal disease.

### Tenth Species.

That diarrhœa which fucceeds the thrush by the falling off of the crusts, and is thereby frequently tinged with blood, is already treated of in the Chapter upon Apthæ. The following remedies are in this kind of great fervice.

R. Sperm.

R. Sperm. Ceti. Mucilag. g. Arab. ana zij. Mixtis adde Aq. Cinnam. S. V. 15 ß. Misce agitando Dr.

The dofe is a fpoonful every hour \*.

Or,

R. Butyr. Ceræ Bat. 3ß. Mucilag. e. g. Arab. 3j. M. terendo & adde Aq. Cinnam. C. Vino. Syr. Diacodii, ana 3j. Decost. Hordeat. perlat. fbij. M. Dr.

The dofe is a spoonful every hour at first, and afterwards after each stool only.

# Eleventh Species.

When the food is carried from the body quite undigested, and runs as it were through the intestines, as soon as received there, the child is then affected with a kind of diarrhœa, commonly known by the name of *lienteria*. This difease is without pain, which circumstance, with those already-mentioned, fufficiently diffinguish it from the other species It is generally in confequence of some other kind of diarrhœa of long duration, bloody flux, thrush in the ftomach, or from any difease which by length of time has relaxed the ftomach and bowels to a great degree, and impaired those juices necessary towards digestion (In Gottingische Gel Anzeigen, nº. 135.): 1 have afterwards found it the learned Dr. Vogel's opinion, that the disease arises from the too great irritability of the ftomach and bowels, by which their peristaltic motion is increased : the cause, as he thinks,

\* Should the cinnamon water be good, it would probably be too pungent, in which cafe we may take 31 lefs of it, and in lieu of it add as much rice gruel.

#### AND THEIR REMEDIES.

is a quantity of *mucus*, or a bilious and four, or fcorbutic acrimony: he propofes therefore as a remedy an emetic and a purge, which ftrengthens the ftomach and inteftines: fometimes *anodynes* are given alfo. He feems to be in the right; this learned man has therefore given a very different view of this and the following diffemper. In difeafes rarely obvious, we are obliged to copy from each other: this is the most dangerous kind, as the body, unable to receive any fupport, must confequently pine away; four eructations are a good fign in this difeafe, as they shew the retention of the food, and its beginning to be digested.

When old people are attacked by this diforder, they are foon carried off.

1. The children of the richer people, may be cured by adhering to the diet I have prefcribed for ricketty ones.

2. Wearing continually on the ftomach the emplastrum stomach. Londinensis.

3. By being anointed morning and night with a little balm of nutmegs on their back all along the fpine : it ought every time to be well rubbed in with a warm hand.

4. Taking every day according to its age 20, 30, or 40 drops of vin. chalybeat. Lond. a little before dinner-time, in fome aq. cinnam. f. v. And

5. By taking night and morning three of the following pills:

> &. Extr. Cort. Cafcarill. Æthiops Martialis Parif. ana Zij. Syr. Cinnamon. q. 1. M.ft.pil.pond. gr. ij. fol. lunæ obduët. Dr.

Spaw water from the Pouhonner spring is also a good remedy in this difease.

Poor people ought to confine their children, as much as poffibly their circumftances will allow, to the above-mentioned diet, and use night and morning the chalybeat wine. In order to render the expence of this wine lefs, they may make it with the white French wine, instead of the Rhenish, and it may also be taken in water where a little piece of cinnamon has has been boiled. *Foreflus* cured one of his relations with a pounded nutmeg, mixed in the yolk of an egg, and afterwards baked upon a hot brick.

A lady being affected with this *lienteria* during her pregnancy, being half gone with child, was cured by half a drachm of the *fabæ* pechurei, feveral other remedies being tried without effect.

## Twelfth Species.

Children are subject to another kind of diarrhœa, which physicians have termed fluxus cœliacus \*. Those who have this difease are affected with gripes, and a violent purging, which is not continued, but comes on now and then, and all at once. Sometimes the excrements have an infupportable stench, and at other times are void of any; their colour is various, as grey, yellow, red, brown, and fometimes tinged with blood. The appetite at times is very great, and fometimes changes into a difgust for food. The patient looks. pale, is lean, pines away, and loses his ftrength; his hands and feet fwell, the ftomach is puffed up, and feverish fymptoms come on; the child is troubled with wind; the mefenteric glands are obstructed; and when the humours become more corrupt, the liver, fpleen, and the large gland lying behind the ftomach fwells, and grows hard; the caufe of this difeafe feems therefore to confist in a corruption of the whole mass of blood, but more especially the digestive humours; because when they are vitiated, they injure the support in the intestines, and make the stomach and bowels lofe their ftrength.

From this we find, that a *fluxus cœliacus* is a fevere, tedious, and obstinate disease; and is either a *cachectic* 

\* The worthy Archiater and Profess. R. A. Vogel, in the year 1768 published a differtation called Fluxus cæliaci genuina notio atque ratio exposita; where he shews that the latter physicians have been mistaken in respect to this difease, and that the milky juice (chylus) is not carried off by the excrements. The great authority of Dr. Ballonius, whose reputation in other respects is well established, has led us all successively into this error.

itself,

itfelf, or at leaft is accompanied with a fimilar one. Emetics given with great precaution are requifite in the cure of this difeafe, fometimes laxatives of rhubarb, and afterwards ftrengthening remedies given for fome time together, as preparations of iron, and good ftomachic elixirs, fuch as I have already given the composition of. The diet recommended in the Chapter upon Rickets, is of infinite use here; if when we have put a ftop to the diarrhœa itfelf, we ftill have reason to suspect, that the glands in the messentery, liver, spleen, or pancreas are obstructed, then the abdomen ought frequently and gently to be rubbed.

When the mefenteric glands are obstructed, and become hard, the ftomach also growing hard and puffed up, it is very difficult to remove, and requires a long time. The whole belly ought then to be well rubbed with a warm hand, or a piece of flannel. The child ought to ride about in a little cart, or carriage, and at times play with other children, and in the open air, whenever the feafon will allow it; its drink fhould be weak mead, or whey curdled by the white of an egg; but this milk ought to be taken from a cow, which has just calved, and has fed upon green grafs during the fpring, and in a pasture where she can get running water, and take shelter under the fhade of the trees. Such milk as this, is the juice itself of the herbs, and has an excellent diffolvent quality, as it is generally fo thin, that it may be drank without being previoufly curdled : if any figns of acidity appear, the child must befides use the pills of offa Helmontiana, (see the Chapter on Rickets), which correct and prevent acidities, diffolve all tenacious humours, and confequently are of use here; but for the cure of the obstruction and hardness in the mefentery, we have fcarce any more certain and powerful remedy than the pil. e cicuta or conio of Dr. Stork, which may be taken from 1, 2, 3, 4 grains every day, and fometimes a larger dofe, drinking after it either weak mead or whey; we must begin with the smallest dose, and increase it according to the child's age.

Should

# DISEASES OF CHILDREN,

60

Should this cœliac flux be occafioned from any cicatrice in the bowels, as fome pretend to have feen, it must be incurable; it feems to me an impossibility that any one should get the better of a dysentery, where the bowels are affected to such a degree as this.

#### Thirteenth Species.

It fometimes happens that children are affected with a diarrhœa, where the excrements are mixed with purulent matter; this generally follows upon a fevere dyfentery, or any inflammation of the bowels, mefentery, liver, pancreas, stomach, or the breast, which not having been refolved, suppurates. We judge by the above-mentioned difeafes having preceded this, that the child has been affected with fome internal boil: for instance, if it has been indisposed, feverish and hot after dinner, or has in the evening its hands hot, red fpots upon the cheeks, lips and tongue dry, little or no appetite, fleep fhort, fweats during the night, its strength and sless emaciated : it is the fame with any internal inflammation, as with an external one; the affected part becomes inflamed, hot, red, swelled, and painful. If the inflammation is not refolved, it suppurates, and the boil is either opened by nature or art, and the matter is discharged : should the tumour or boil not burst of itfelf, and from our neglect have been prevented (thro' fear of hurting the children, natural among parents) from making any incision, the purulent matter (pus) becomes acrid, thin and corroding, is gradually abforbed into the blood, caufing fmall irregular fhiverings, and a confumptive fever; the blood in the mean time grows corrupt, lofes its gluey and nourifhing quality, just in the manner as when the white of an egg (album ovi) putrifies : the body and strength both confumes, the humours by being exhausted decrease, night fweats come on, and at last an incurable diarrhœa, which phyficians call colliquativa, becaufe the blood is melted away as it were, which is in confequence of this Thirteenth Species we here treat of, and is fometimes called diarrhæa purulenta. It fometimes times happens, but not once in a thousand times, that the suppurating matter being taken up by the absorbent vessels, and entering the veins, does not mix with the blood, but is carried along with the circulation to the reins or intestines, is there emptied, in the first case along with the urine, and in the latter with the excrements. An instance of this kind is to be seen in *Misc. Nat. Cur. Dec.* 2. Ann. 2.

A boil in the loins disappeared in the night preceding the day it was intended to be opened, and the purulent matter was carried off by stool. In the same work, Dec. 3. Ann. 2. obf. 2. p. 6. is mentioned a large swelling (tumor) on the arm being cured by purulent stools. See also An. v. & vi. obf. 281. p. 635.

But few are fo fortunate as this, nor do we know any remedy that is able to prevent the blood's mixing with the purulent matter : in inflammatory difeafes the blood has acquired a quality of not mixing with the water the patient drinks, it running off quite clear and colourlefs; if we mix any thing of a foapy. nature, for inftance fugar, or electuary of currents, or fuch things, it then enters the blood.

Internal ulcers, from whence the matter has not a free and eafy iffue, are incurable. We are hardly able to cure those from whence the discharge is free.

If the ulcer is in the bowels, or mefentery, or at least discharges into the intestines, we have yet some hope less, unless it has already corroded through the guts, and part of it enters the blood.

The number of glands in the inteffines are the reafon of these ulcers becoming so often cancerous; we have however some inftances of wounds in the stomach being healed up; but when they are in the liver or lungs, we have scarce any hopes of a cure, unless we know they are only upon the superficies of those *viscera*; as that part of the lungs may the nadhere to the *pleura*; or the diseased part of the liver may become attached to the adjacent parts, which generally happens during the time of inflammation. If a free discharge of the matter is procured by any external incision, the ulcers by this may be kept clean and healed : we have instances of this; otherwise we must endeavour to draw away the purulent matter by by fome corroding remedy; for inftance, apply externally (caufticum) an artificial ulcer (fontanella), or a fetaceum, opposite the part affected. This ought to be done foon, and before the matter has acquired an acrimony, or corroding quality, or has began to enter the blood, and vitiate that fluid; fome few fuccefsful cures of this kind ought to encourage us to try further these remedies.

From what has been observed, it plainly follows that a purulent diarrhœa ought not to be ftopped : if the matter goes off whitish, and of one colour, we may-hope for a cure. All that we can do, is to order the patient a very austere diet, to abstain from all hard and falt food, meat, and whatever occasions a heat; and that in the fpring he must live only upon the whey of fuch milk as has been above-mentioned; afterwards upon butter-milk, water gruel, thin foups in which plenty of greens, as fpinnage, chervil, endive, forrel, &c. has been boiled, and afterwards strained off. Seltzer water (aq. Zeltherana), mixed with milk; tifans of the Switzer herbs, with milk and a little clarified honey: fhould this be attended with gripes, we must then give towards bed time fome paregorics; for instance the confect. Japonica Edinb. or some similar remedies. If the diarrhœa is violent and frequent, we must then give some rheum tostum, succus catechu, Æthiops Martialis, cafcarillæ extractum, or fuch things, although by this we occasion the purulent matter to enter the blood; but neceffity has no law. Balfamic remedies, fuch as balm of Peru, myrrh, ftyrax, &c. I have never as yet found of any fervice; they heat confiderably, increase the inflammation in the margins of the ulcers, and also the purulent matter by which the ulcer grows larger. We may expect fome relief from the Jesuits bark with honey of roles given between the paroxyfms of the fever. A child that had a diarrhæa purulenta after a chin-cough of long duration, was cured by drinking a tifan of rofes, milkwhey, and a little honey, and continuing its use a long time. An officer was also kept alive 7 years by this diet, his difease being an ulcer in the liver; all this time he was almost able to do his duty; he was at last affected with a dropfy (anafarca), and though the

the water was evacuated three times, it however got the better of him. He was opened after death, and a large ulcer found in the liver, which had burft, and discharged itself into the gall-bladder (vesica fellea), and from thence down into the inteffinal tube. A nobleman of a middle age, being affected with this kind of diarrhœa after an inflammation in the liver (hepatitis), lingered for the space of eight years by means of the fame diet, and died at last quite emaciated of a confumptive fever. His diarrhœa was fometimes fo violent that I was obliged to ftop it, which could not be done by any other remedy than roafted acorns beat into a powder, and taken in water... I was also called to a gentleman towards the close of his life, who was affected with an ulcer in the bowels, and a painful diarrhœa of long duration. He was only 27 years of age, and all my efforts to cure him proved ineffectual. His constitution had always been ftrong, he had taken very little care of his health, but abused it in every respect, once especially very. rashly exposing himself to the cold, ever fince which his excrements became loofe, in colour brown and tinged with blood, but without gripes. In hopes of freeing himfelf from this painful difease, he had according to the advice of fome perfon or other, drank whey curdled with alum, from whence arofe pains in the bowels, and gripes; a hardness remained in the right fide, and an obstipation for ten or twelve days, which could not be relieved by any laxatives; but was affected mostly for the space of half a year with costiveness. At last a shoemaker promised him a cure; this quack brought out of the fea fome loggs of birch wood foaked through, putting them into an oven previoufly heated, and placing them in an oblique direction, fo as to collect that milk-coloured juice, which was expelled by the heat, and received into a veffel below. The patient drank once of this preparation without effect, and three days after repeated it, and from that time was affected by the most painful rumblings of wind in the ftomach, accompanied by a diarrhœa, and fuch violent gripes, that he frequently bit feveral holes in his tongue, as feveral marks were to be feen thereof afterwards. Sometimes water was evacuated with his ftools.

ftools, and fometimes purulent matter of various colours, and fometimes refembling bloody glands. Towards the end of his life he had a flight confumptive fever, his legs fwelled, and every other part of him was merely fkin and bone. Nothing afforded him more relief than the *elect. è fcordio.* or *confect. Japonica Edinb.* which only lafted eight or ten hours; but when during the night he had fometimes 70 or 80 ftools, I was obliged to let him chew and fwallow a quantity of roafted peafe, burnt in the fame manner as coffeebeans. The effect of this was, that he was always freed from the gripes and ftools for upwards of three days together.

## Fourteenth Species.

We have already mentioned that fort of diarrheea appearing at the end of confumptions, or a dropfy, or where the purulent matter, from any internal or external ulcer, has entered the blood, and melted it as it were. It is called diarrhæa colliquativa, and is incurable; all we can do in this cafe, is to prolong the patient's life for a little while, by applying finall clysters of milk with starch, in which we may put a little brandy; or 10, 15, to 20 drops of Laud. liq. Sydenh. or we may prepare one of half a pint of milk, 3 ß of theriaca, or of lime-water, confect. Japonica, and balf. Locatell. previoufly diffolved in the yolk of an egg. I have known half a drachm of the Faba pechurei taken now and then to relieve fuch a diarrhœa for a fortnight in a patient dying of a confumption, though I must confess it has frequently failed.

## AND THEIR REMEDIES.

# CHAP. XII.

# OF THE SMALL-POX.

T is uncertain, at what time the fmall-pox first made its appearance in Sweden; but it is very well known, that it first came from the Arabs, from thence went to the *Ægyptians* in the year 622, or 640, and into Spain in the year 714. It was already a difeafe generally known in England, in the year 1270, or 1280. From Europe it was carried over to America; from Denmark into Greenland. This difeafe has always been found exceedingly lethiferous in places, where it appeared for the first time; and becomes milder after having continued there for fome time. Nevertheless more people are carried off by it, than by the plague.

Ever fince the introduction of the finall-pox into Europe, it has always remained there, and fpread from one place to another. The contagion is more obvious in large towns, as people in greater number, and from many different places, refort here. Likewife in univerfities, as many young people are collected there from various parts. One fingle perfon may convey the contagion to a place, either by his baggage, or by being infected himfelf. Hence we learn, why the small-pox fo feldom appears in nunneries.

In the month of February, in the year 1755, there was not one fingle perion in Upfal affected with the imall-pox. A student conveyed it there from Oerebro, this latter place being infected, confequently the contagion was conveyed from Oerebro to Upfal. Another student was infected, and died; his brother went from Stockholm to Upfal, in order to take care of the burial, and carried the infection with him, in returning to Stockholm again.

In the year 1718, a Dutch ship went to the Cape of Good-Hope: three children who had lately had the Imall-pox were on board of it. At the arrival of this thip, the linen which was used during the difease, F

and

and which had been put by in a cheft, was fent ashore in order to be washed. Those employed in washing them, became immediately thereby infected, and the contagion fpread further up in the country, and did not ceafe until the Hottentots threw up a wall, and keeping watch there, prevented all human beings from advancing further inland. This put an effectual ftop to the difease.

From this we find the fmall-pox to be a contagious distemper, affecting only those who have not had it before, and in whofe fluids there is a disposition to receive the infection. Thence we justly conclude, that the poifon of the fmall-pox is not bred in the air, neither propagated by that element; and that a village or town might be preferved from the fmall-pox, if the fame precautions were taken against that difeafe, as against the plague. Nay, a whole kingdom would always be freed from the fmall-pox, if all those who have not yet been infected, were inoculated at a time: their clothes which they had used during the disease, ought to be buried in the earth, and the infection should likewife be prevented in the same manner as in the plague.

It likewife appears from this, that when the fmallpox is in one or two houses of a town, there is not any inevitable neceffity that it should spread further; it certainly may be avoided, if fuch dry nurfes only are chosen, who before have had the difease; the cloaths of the patient afterwards buried, and the intercourfe between the houfe of the patient and others prevented for fome time. This at leaft would preferve others for a time, till the infection is conveyed there again from other places.

The fmall-pox is propagated,

r. When a perfon who has not had the difeafe, vifits any one who actually is infected, then touches him, or abforbs the contagion by the breath, or by the pores of the skin. I have myself sometimes obferved, that eruptions fimilar to the fmall-pox have broke out on those, who have nursed patients during that difease, or have sat by their bed-side for several days together; but fuch eruptions were attended with no fever, nor did they leave any marks after them. A

66

A fimilar and very remarkable instance may be read in Philosoph. Transactions, No. 373, and another No. 390. Dr. Kirkpatrick mentions that he, on fuch an occasion, got a pustule on his upper lip." See his Analysis of Inoculation, edit. ii. p. 21.

2. By handling the clothes of the patient: it is not ascertained for how long a time the infection will adhere to clothes; and preferve its activity; but this we know, that it may be preferved over all the winter, and the next fpring be fit for inoculation, if during that time it has been fhut up in a close box. Therefore it feems possible that a perfon, who has not yet had the fmall-pox, may be infected by handling linen or clothes, which have been ufed during that difeafe, notwithstanding they may have been put by for some time amongst other clothes.

. 3. By being bled with the fame lance that lately. has been used for a person affected with the smallpox. In the year 1741, Mr. V. G. was bled, the lips of the wound fuppurated, and grew fore, after which he got the fmall-pox. The fame happens in an inoculation.

4. By purchasing; as has been customary in Saxony, in East and West-Gothland, and in the principality of Wales; in the former places the child is carried to a perfon, who has a benign fmall-pox, and any one defires to buy five or feven puffules. The money which has been agreed upon is put, one piece after the other, on a ripe and broken puftule, in order that some of the matter may adhere to each piece; these coins are then tied to the legs of the child, and thereby a part of the matter is abforbed through the pores, and caufes the fmall-pox. In the latter place, the fkin is pierced with a pin, and fome of the matter is put on the wound. Both these methods are in reality a fort of inoculation.

5. By inoculating as the Chinefe do: they promote the infection by dipping a piece of cotton in the ripe pustule, and afterwards putting it into the nofe.

6. By inoculation in the Circaffian manner: this is a method now very much improved by the English, and made use of, both by them, and many other na-tions, with great success. The excellent reflections by F 2 Mr.

Mr. Condamine on the inoculation of finall-pox, tranflated into Swedish in the year 1754, by the care of his Excellency Count Scheffer, Great Counfellor of the kingdom, merit a careful perusal.

The small-pox is very difficult to know in the beginning. One may affert it to be that disease,

I. If we hear that the fmall pox is now rife in the neighbourhood.

2. If we know that the patient has not had it before, and has been lately in the fame room where a patient lays with the fmall-pox, or who lately has had it; or if he comes near a perfon who a little before has visited a patient affected with the fmall-pox, or touches, or wears such clothes as are infected.

3. If those figns appear, which generally precede exanthematic fevers; such as weakness, without any apparent cause, chilliness and shivering, with a succeeding heat, pain in the loins, heaviness across the breast, and an inclination to groan.

4. We are still more convinced that the patient is infected with the small-pox, if his face seems to be puffed up, he feels a heaviness over his eyes, and some tears flow, especially from the left eye; but these being now less hot than in the measses: besides, if he feels a pain in the pit of the stomach, when it is preffed with the hand, has likewise a dulness, and great propensity to sleep, even on unusual hours, or has startings during his sleep, and a great inclination to vomit \*.

The

\* The warthy or flony, and the chryftalline or watery Imall-pox, break out within 24 hours, and difappear within five, or at most fix days. The eruptions of the former fort are hard as floues, and may leave fome fcars after them; the latter refemble clear water-bladders. Before breaking out, they are attended with anxiety in fome perfons; but after the eruption, the evil is generally over. A lady 48 years old, became affected with both thefe forts at once, accompanied with fo great an uncafine is and anxiety, even after the eruption, that every one prefent took it to be the true finall-pox. The report would certainly have fpread,

The fever continues, but not equally violent, till the breaking out of the puftules; a little before that, fome children become convulfive, which is commonly a good fign \*, or fignifies a benign fort of fmallpox, provided the child is not befides affected with a difficult dentition. Thefe days conftitute what is by phyficians called the first *ftadium*, or *period*, and which contains fomething more than 72 hours, or takes up a fmall part of the fourth day.

About the fourth day, the fever begins fomething to abate, and 'immediately after the eruption follows. It appears like fmall red fpots or pimples, refembling pin-heads; at first they break out in the face, on the upper lip, on the fides of the nofe, afterwards on the other parts of the face; then they come out on the breaft, arms and hands, and at laft on the thighs, legs and feet : but they feldom break out on the belly, as the skin is there very tough; neither under the feet, as the foles of the feet are thick on those who have walked much, and efpecially without fhoes. These above-mentioned eruptions increase by degrees, grow more elevated and broader, with a white point or fummit, and their bafis red; the spaces between the pustules turn likewise red. The whole body seems puffed up, the face begins to fwell, but chiefly the eye-lids, fo that they with difficulty can be opened: proportionably as the puftules increase and grow elevated, the fever decreases, as does also the vomiting; both of them difappear as foon as the eruption is compleated; those days are by physicians called the second stadium, or period, and is of forty-eight hours or two days duration.

fpread, that fhe was affected with the fmall-pox for the fecond time, had not I myfelf, together with feveral other phyficians, feen and known the difeafe. The fame is perhaps the cafe with all thofe, who are faid to have had the fmallpox twice, or feveral times; therefore phyficians ought not to affert any thing, but what they have feen themfelves.

\* Nevertheles we have inflances of those, who have lost the use of speech, and become paralytic, though they have sooner or later recovered from this. See *Kirkpatrick*, c. i. p. 84.

F 3

The

The third period takes its beginning when all the puffules of the face are broke out, and is finished or at an end when they begin to dry. This period commonly continues till the eighth or ninth day, during which time the puffules begin to ripen and look yellow; that is, they suppurate, or are filled with pus, grow elevated and broader, their bases are red and painful; the fkin or interffices between the puftules continue reddifh, the fwelling in the face increafes, fo that the eye-brows cannot be opened; therefore one is faid to be blind till the fwelling fubrides again. The eyes can then be opened and fee as before, which happens on the eleventh day: when the fwelling of the face abates, it goes into the hands and fingers, and at last into the feet. In this stadium or period, the fever returns again, except it is a very be-This fecond feyer is called nign fort of small-pox. the suppurative fever.

The fourth period begins on the eleventh day, or from the time that the pustules begin to be incrusted or fcab, and continues till the fcabs are fallen off. The puffules are now drying, scaling and falling off in the same order as they broke out; during this time, it often happens, that a part of the variolous matter or pus has not transpired, but is absorbed into the blood, and caufes another fever, which phyficians commonly call febris secunda variolarum, tho', ftrictly speaking, it is the third fever of the small-pox; but as it fometimes begins, when the former one fcarce has gone off, it is no wonder that they are confounded. The disease sometimes is so favourable, that neither the first or the second fever is observable. A true Imall-pox never is finished under eight days.

This is the run of the difeafe (decurfus morbi), when the pocks are benign and regular; but when they are of a malignant kind, they will break out within 72 hours, and not by degrees, but all at once, and in a large quantity; in fine, they likewife come out in the nofe, and make a ftoppage there, as alfo in the throat, and caufe a great difficulty in fwallowing. The eruption of the puftules is not performed in the fame manner and order, as above was mentioned of the other fort, but begins as well in other

other places as in the face; they are of a finall fize in the face, but nevertheless they often run into one another, partly in confequence of their great number, partly by their being fituated too close to one another in feveral places, and therefore broken out in heaps, or in bunches. They do not turn yellow or ripen, and are confequently not filled with pus; therefore they cannot grow elevated and pointed, but are flat and depressed in the middle : if we open the one or the other of them on the twelfth day, still only a water is difcharged ; befides they put on an unufual colour, as green, violet, or black. The fkin looks on the eighth or ninth day like parchment; the small-pox is likewife of a bad kind, if it is complicated with a difficult hæmorrhage, or petechial fpots, or with pleurify. The fever which otherwife should cease when the eruption is performed, continues here The other fuppurative fever does not come on ftill. gradually, but all on a fudden, and with violence. The fpitting begins already in the fecond period. The saliva becomes more and more tenacious, at last it is fuppreffed, and may fuffocate the patient. I find that Doctor Schröder has made some well founded remarks and objections against the common method of dividing the small-pox. See Gott. Gel. Anz. 1770, p. 1145. They merit a careful perusal, as does every thing this worthy man has written.

When this difease begins to spread in any place, it is difficult to tell whether it will turn out a fevere or gentle kind. It is commonly more favourable at the beginning and at the end of the contagion; but this is not a conftant rule, for the one which began at Stockholm, in the year 1751, in the harvest, and continued till the fummer in 1752, was in the beginning gentle, but the reft of the time it remained malignant : if some other kind of epidemical difease infests the place at the same time, the finall-pox will then turn malignant; but when it has continued a long time in any place, it generally changes into a more benign one. The longer this contagion reigned in Minorca in the year 1746, the less mortal it was; in short, sewer people died of it at the northern part of this island, where the difease made its appearance last, than in the fouthern part, where F 11

it began. When it is a long time paft fince the contagion before infefted the place, it will then act more feverely; and therefore being conveyed to this above-mentioned ifland in the year 1742, it was very lethiferous, as it had not appeared there fince the year 1725. It has been a commonly received opinion, that when the contagion comes into a houfe, those would be the worst off, who last get infected; but I have frequently observed the first attacked were worse. Some years ago, fix children in one family got the some years ago, fix children in one family got a very bad and confluent fort; the other, who had the infection from the former, got it very gentle, &c.

We may judge any particular perfon to get a benign or malign fort of finall-pox, either by what already is faid, or from the following circumftances : a perfon has reafon to expect a benign fort, if he is middling fat, has a mild blood, foft and white fkin, florid complexion in the face, a mild and chearful countenance, the eyes being befides clear, but not fiery. We fufpect the patient will have a bad fort, if he be lean, has a dry thick and hard fkin, brown or black hair, dark or funken eyes, and if his voice is hard and fonorous.

If one get affected with the fmall-pox, when the body is well prepared, the ftomach and bowels being well cleanfed juft a little before, then one may expect to get through the difeafe more eafily, et è contra. It likewife is probable to have them gentle if they are caught in the beginning of a flight contagion; but after it has continued fix or feven weeks, it may turn out a worfe fort. One may expect to have a tolerable kind, when the contagion has been malignant in the beginning, and one does not fall in until after it has continued there for fome time.

Those will get a bad kind of fmall-pox, who live much on meat, either use too nutritious, or too weak a food, or have lived too freely, in respect to eating and drinking, and night-watching, or have had too strong exercise, or if they previously have been enervated by some disease or other. If a woman big with child receive the contagion, she herfelf, or her  $forms = \frac{1}{2}$ 

fœtus, or both of them, run the rifk of lofing their "lives; the fame is the cafe, if fhe becomes infected at her lying-in \*.

Tho' a child has had much itching or fcabs, it does not get lefs pocks for all that, but on the contrary has rather more; likewife it will be affected with a greater number of them, if a little before, it has had the miliary fever: if a child before this difeafe is affected with a quotidian ague, and it gets the fmallpox, then the former difeafe will generally ceafe.

Those who have soft fibres, have the small-pox more benign than those who have rigid ones; therefore *Englishmen*, who bathe much in cold water, have got severe pocks, and the *Negroes* still more so, as they, besides bathing, ancint themselves with balms, rosins, and similar substances, which obstruct the pores.

. Young people go through this disease with more facility than old perfons, and the younger they are, the more fuccefsful generally is the cure. Nevertheless we have instances of children, who have got a malignant fort of small-pox, and died, tho' they still were not weaned; but the fault may then lay in the nurse, or nursekeeper; for instance, how should the child be preferved, if the nurfe at that time eats much meat, is of a bad temper, or is in love; or if she has her menses, fits in a place to swaddle the child exposed to the draught of air, or fwaddle it feldom, and that in linen not warmed, tho' it fhould have wet itself; or if she lies down on the floor, and takes the child by her, &c. If this befides happens at the time of teething, the child can hardly by any means be recovered; if pocks fettle in its mouth and throat, or on the lips, it is thereby prevented The most favourable age for a patient from fucking. in the fmall-pox, is from the fourth year to the fourteenth, and the next favourable one from the 16th to the 25th.

\* Kirkpatrick, c. i. p. 316. has written down a cafe, which feems promifing to women, that they may happily go through the fmall-pox, though the eruption fhould fall in at the fame time with their menfes.

I have

I have myself observed fat children to be as often favoured with a mild kind as lean ones.

If the puftules being licked, have a falt tafte, the child that has them, is commonly expected to die, but not elfe. It is likewife faid, that the difeafe willbe fevere, if the hands and feet fhiver in the first *ftadium*, or period, on their being touched : if those who have fed well, lose much blood just before their falling in, either by wounds or otherwise, they will commonly have a favourable fmall-pox \*.

It is no good fign if a loofenefs comes on, juft at the time of eruption, and continues ftill fome days during the breaking out of the poftules. If the pocks itch immediately after their coming out, they will not be mild. When the pain in the loins, and the vomiting is gentle, no very offenfive fmell comes from the mouth, the nofe not obftructed, and the throat clean, the fmall-pox will then be benign, et e sontra.

Hæmorrhages of the lungs, and of the anus, are threatening figns; but the blood being voided along with the urine, not one patient among a thoufand will recover. In the fmall-pox, attended with petechial fpots, three fick are fometimes carried off out of four. A confluent fmall-pox kills fometimes every fourth or fifth of those thus affected.

We fear a bad event if the puftules in the face are flat, and have a deprefiion in the middle, together with a black-fpot, and if their bafis either be dark red or pale, and indolent in the third period; not round and hard to the touch, but foft, as alfo to the appearance, as if they were wrinkled or empty. Neither can we hope for any good fuccefs, if the

\* Dr. Fuller relates, that a fludent at Oxford got the finall-pox, attended with an hideous pain in the head and loins, as alfo a *delirium*; but was relieved from all thefe by a violent hæmorrhage. A child feven years old, loft a great deal of blood by its flools, a little before the eruption of the puffules, which turned out a very mild fort, though the contagion was at that time fevere. This Mr. V. Haller tells in Opufc. prin. iii, p. 352. Kirkpatrick, c. i. p. 98.

patient

patient frequently makes water, and but very little at a time : if the urine then looks pale, *delirium* and convultions are imminent, unlefs the patient has lately been bliftered with a plaifter of cantharides.

A diarrhœa in the three first periods does no good, but is often of fervice in the fourth period; but if that which is carried off looks purulent, or is mixed with blood, or is black, the belly being diftended and fwelled with fome pain, then a gangrene has already taken place in the bowels: it is bad if the fuppurative fever does not come on by degrees, but all at once, and with a hard pulfe, pain in the head and eyes, which are red for want of fleep (agrypnia), and much uneafinefs: if we then obferve a hard pulfation in the arteries on the neck, a delirium will follow; but death itfelf is generally the confequence, when the pulfe at the wrift of the hand is low at the time the above-mentioned blood veffels are beating hard.

If not only the whole face, but the eye-brows and the lips fwell, it is a bad fign; but the patient will very foon die, if the tumour or fwelling of the face withdraws haftily, and does not immediately go to the hands; if the fpitting ceafes, the fkin which is between the puftules and their bafes turns pale, he likewife being fhort of breath, his voice altered, with a peculiar hoarfenefs, and if he is alfo obferved to be forgetful.

When he has many puftules in his throat, what he drinks returns through the nofe. This is the caufe of children being fo much against drinking during the small-pox, and is in that respect chiefly dangerous, as they cannot take the medicines, though in this disease, unless we drink plentifully, death enfues.

A fevere cold coming on while the difeafe is ftill in its third period, will eafily fupprefs the fpitting in a fevere fmall-pox; many are faved by getting large boils, provided they are obferved and opened in time.

I. When one gets the fmall-pox at the beginning or the end of its contagion.

2. When the contagion is benign.

3. When it is but lately fince the contagion of the fmall-pox appeared before in that place, where one now is affected with it.

4. During the spring or autumn.

5. When the body is well prepared, and the ftomach and bowels well cleanfed.

6. When we are otherwife healthy, and of a ferene temper, and the body in no way overloaded.

7. When no other epidemical difeafe is fpread in the neighbourhood. Unfavourable Signs of the Small-pox.

1. When the contagion of fmall-pox has already fpread much.

2. When the contagion is malignant.

3. When the contagion has not appeared there for a long time before.

4. During a warm fummer, or a fevere winter.

5. When the body is not well prepared, and the ftomach and bowels not well cleanfed.

6. When the fluids are in a bad flate, one has the milliary fever, fcab, boils, and worms, or is emaciated by fome difeafe before, as forrow, night-watching, much care, or overloaded with ftrong liquors, and by improper food.

7. When other bad contagious diftempers infect the place, fuch as the petechial fever, milliary fever, pleurify, and peripneumony.

8. When

## AND THEIR REMEDIES.

#### Favourable Signs of the Small-pox.

8. When one is not too fat, has a foft and white fkin, lively complexion, a mild and chearful look, bright but not fiery eyes.

9. Above four years of age, and paft the age of a tender infant.

10. When one is of a family, who commonly have had the fmall-pox mildly.

11. When a woman is not pregnant.

12. If the has been well the first three days.

13. When one is between the fourth and the fourteenth year of age.

14. A middling quantity of blood, or difcharge of that which was fuperfluous, either by hæmorrhage from the nofe or otherwife.

### Unfavourable Signs of the Small-pox.

8. When one is lean, has a rough fkin, which is thick, hard, or is of a brown complexion, a heavy look, the eyes being dark and deep, down in their orbita, the white part of them reddifh, black hair, harfh voice.

9. Not yet four years old.

10. When one is born of a family, the greater number of who have been affected with a malignant kind.

11. When a woman is big with child, or brought to bed.

12. If the has been rather indifposed the usual time.

13. When one is in the fourteenth, fifteenth, or the fixteenth year.

14. Blood in too great a quantity, or too rich, or too emaciated.

77

15. When

15. When one has not been very fond of meat.

16. In the beginning of the illnefs has ufed proper remedies, been well taken care of, and drank freely.

17. The bed place in a large room, which is moderately warm, and free from any draught of air.

18. In the first period, the heat, the headach, and thirst but moderate.

19. In the mentioned period, either has no vomiting at all, or a very gentle one; feels no pain in the *abdomen*, nor too great loofenefs at the time of eruption.

20. When the patient is but a little or not at all delirious, has a regular fleep, and the uneafinefs is moderate. Unfavourable Signs of the Small-pox.

15. When one has lived much on animal food.

16. Neglected, and ill nurfed in the first periods of the disease, and drank but little; for one must drink much, or else we die of the small-pox.

17. Sleeping in a narrow place, where one is exposed to the draught of air, to a great heat, or to much cold.

18. When in the first period one is affected with much heat, thirst and profuse fweat, likewise with fevere pain in the head and back, also a shivering in the hands and feet, upon their being touched.

19. Has a violent vomiting, with a pain in the *abdomen*, and too great a loofenefs at the breaking out of the puftules.

20. Has a fevere delirium; which is of long duration; too much fleep or reftlefsnefs, much uneafinefs, frequently changing his pofition in the bed.

21. Slight

21. Slight startings or convulsions a little before the eruption of the pocks.

22. Moderate bleedings at the nofe.

23. When the fmallpox do not break out fooner than after 72 hours or three days, and then by degrees; first in the face, afterwards on the breast, arms, hands, legs, feet. Are few in number, especially in the face, so that the puscules are pretty diftant from each other.

24. When but few puftules fit on the nofe, and none in the infide of it, or in the throat,

25. When the fever goes away after the eruption is performed.

26. They grow elevated and pointed, are round and large, have the usual colour, white point, red bafis, Unfavourable Signs of the Small-pox.

21. A stinking smell from his mouth.

22. Too great a lofs of blood from the lungs, by the ftools, but chiefly by the urine.

23. When the eruption is performed within 72 hours, fuddenly without any order, and the puftules are in great number, efpecially in the face, fo that they grow confluent; and that they itch immediately after the eruption.

24. Too great a number both in the infide and outfide of the nofe, and in the throat, fo that the patient is obliged to breathe through the mouth, and has a difficulty of fwallowing.

25. The fever still continues, after the pussules have broken out.

26. When they are fmall, oblong, or angulated, or ftand clofe upon one another, do not grow ele-

bafis, and the fkin red in the interffices of each puftule.

27. None, or but a flight féver in the third period, good reft and eafy breathing.

28. If in the third period the puftules turn yellow and ripen, are diftended, hard to the touch, and painful, that the body feels fenfible.

29. And no fpitting in this period; or in cafe it comes on, it is but thin, eafy and continued.

30. When the fwelling of the face is but little, or equally fpread all over, fo that even the eye-brows cannot be opened.

## Unfavourable Signs of the Small-pox.

elevated and pointed, but deprefied in the middle, together with a black fpot, and the bafis of a dark red or pale, as alfo a pale fkin in the interfpaces of the pocks, get an unufual colour, as green, violet, or black.

27. A fuppurative fever, which comes on not by degrees, but on a fudden, and attended with a headach, reftlefsnefs, red eyes, continually changing pofition in the bed, a *delirium* and afthma.

28. If they do not ripen foon, and turn yellow, but appear as if they were empty and wrinkled, are foft on feeling them, and not painful.

29. Strong falivation from the beginning of the eruption; that which is hawked up is vifcid, and done with difficulty, or fometimes ftopped , at once.

30. Many puftules without fwelling in the face, or only the eye-lids, and the lips tumid.

31. When

31. When the fwelling of the face gives way on the eleventh day, and goes to the arms, hands, and fingers, and at last to the legs and feet.

32. Mild weather in the third and fourth period.

33. If the puftules eafily dry in the fame order as they broke out.

34. When one has fome ftools during the confluent kind, or in an otherwife bad fmall-pox, likewife fome loofeness in the 4th period, and finding relief after each stool.

G

Unfavourable Signs of the Small-pox.

31. Or a large tumour comes on, and fuddenly fubfides without immediately taking its way, or going into the arms; hands; and fingers, and at last to the legs and feet.

32. Severe cold in the third and fourth period, by which the fpitting diminifhes.

33. If they will not dry, or do it but flowly, and get new crufts for the fecond and third time, fince the former have fallen off.

34. When one gets no ftools in the fourth period, or too ftrong a flux attended with pains, without finding ease, so that the ftools look nafty and purulent, and are mixed with blood; the ftomach is distended and tumid, with a fense of pain : for the gangrene is then in the bowels; the patient feldom voids his urine; and but little at a time. If the urine is made frequently; but little and of a pale colour, then a *delirium* and convulsions will enfue, unlefs this arifes from his being

Unfavourable Signs of the Small-pox.

being bliftered with cantharides. A *delirium* is imminent when the arteries on the temples and neck are beating quickly: if the pulfe at the joint of the hand is neverthelefs weak at that time, then death will follow.

35. Boils in the fourth period, which have been neglected, fo that they are not ripened and opened.

36. If he has at this time a difficulty of fwallowing, a peculiar hoarfnefs, and with a hollow voice.

37. A black tongue, thrush, defire of sucking of the cloth, which is sprinkled with wine, or any scented water.

38. Pains in the bowels.

39. When nature does not yield to the remedies, and they have no more effect, the water is voided without the knowledge of the patient, and the fame is the cafe in refpect to his ftools: he gets hiccup, the fweat comes out in

35. No boils.

36. The patient fwallows eafily in the fourth period.

37. Clean tongue.

38. No pair in the inteftines.

39. When nature obeys the remedies.

#### Unfavourable Signs of the Small-pox.

drops, which grow violent and cold : then he gets convulfions and at laft dies.

# The First Period.

When any one catches the fmall pox he ought to begin immediately to take remedies; what is used the three first days is the most necessary part of the whole cure; if that be neglected, and the small pox are malignant, the physician can in fuch case promise no favorable event. No difease requires so much nicety and carefulness, as this; a cold breath of wind, a cold napkin; or plate; may cause the pushules to subside or re-enter the body; a cold drink, or foured whey; will sometimes suppress the spitting. If one does not continually prevent the patient from scratching himfels, he may be hurt and deformed for the rest of his life-time; if one during the time that the pocks are feabbing does not continually take notice and care of the patient's eyes, his fight may be endangered also:

The fmall pox would eafily be cured, provided we had fome antidotes against the variolous matters which could fuffocate or destroy the possion in its first beginning; till any such antidote is discovered; or the inoculation of small-pox is universally received, we shall be obliged to follow the disease through all its stadia or periods; and must in each of them endeavour to relieve the patient to the utmost of our power. Before I undertake to describe the cure itself, it will be necessary to mention some circumstances, on which the happy event of the disease may in a great measure depend.

1. As to the room in which the patient lies, it would be beft to have it large; middlingly light; neither too warm nor too cold; but free from any draught of air. If the patient has a fevere fever, the room ought to be kept cooler; and if the fever be too flight; the  $G_2$  room room should be something warmer. The temperature is generally as it ought to be when the Swedish thermometer stands 13 or 14 degrees above the freezing point \*, or when one fearce feels any chillinefs in the fingers on fhaking the hand haftily backwards and forwards. It is likewife of fervice to hang a curtain before the door; partly to prevent the draught of air, and partly that one may let in fresh air : without this a draught of wind will incommode the patient. One ought also frequently to ftrew young and fresh branches of Scotch fir-tree in the room, and which antecedently have been chopped and sprinkled with some small beer or vinegar, or with a little rhenish wine, in case the patient is weak. The fick will fuffer in his eyes if the room fmoaks, but he will find immediate relief by fome vinegar evaporated over the fire. We ought not to place more than one or at the utmost two patients in the fame room, unlefs we cannot poffibly avoid it. We know what a stench arises from a fingle patient, especially on the 8th or 9th day, and that, from several' patients in the fame room, the air grows infected to fuch a degree that even the healthy fuffer by it, and the fick still more fo. In that case, it is not fufficient to use the fir or spruce, as above was said, but one ought even then frequently to put some vinegar over a fire-pan in order to evaporate in the room. The bed ought to be fo placed that one can get to the patient on both fides. It fhould especially not be put near a stone-wall; for it is obferved that the pocks ripen and dry much better on that fide, than on that which is towards the room itself. Nor ought the bed to ftand fo that the light falls in the eyes of the patient; he may lay on his usual bed cloaths, but a matrafs is in general the He should ase a thinner covering if it be in the beft. fummer, and a thicker one if it be in winter; his feet ought to be kept fomething warmer than the other

\* The Swedift thermometer is filled with quickfilver, and the diffance betwixt the boiling and freezing points is divided into 100 equal parts or degrees, which one muft begin to count from the freezing point, both ways, upwards and downwards.

parts

parts of his body. We fhould by all means fhift the fick with clean linen, especially in the fourth stadium, provided it is carefully and cautioufly done. There is no necessity for any persons wearing it before, it will be quite sufficient to have it well dried by a smoothing iron; or if his linen happens to adhere to any of the pustules during the disease, we easily loosen it by applying to that place a fpunge which has been dipped in warm milk.

Nobody ought to be admitted into the patient's chamber who is not wanted to the nurfe-keeping, and the lefs we talk with him the better it is. As for the food, we observe in general, that a fick person ought to eat but a little at a time, and never to take any folid food at those hours of the day when the fever is fevereft. He does not want much nourishment in the favourable kind of finall-pox, becaufe the illnefs will be fhort. But in the feverer fort he has occasion for more, as the difease will be of long duration ; all forts of water-gruels and groats are convenient, as also a cherry-foup. Those who have a thin blood and little fever, may eat veal and chicken-broths boiled with greens, and afterwards ftrained : or panadas prepared for instance as follows. Take two ounces of biscuit, boil them in a pint and a half of water till they are well diffolved, then add two or three spoonfuls of wine, and two drachms of fugar, beating it together with the yolk of an egg on taking the pan from the fire. Those on whom the pustules will not rife and fill well, may be allowed fome wine in their foups, or they may eat a flice of toafted bread foaked in water, ftrewed with fome fugar, and fprinkled with a little rhenish wine. If the patient has too great a loosenes, give him this toalt strewed with the yellow part of orange peel, a little nutmeg and cinnamon. When the fever is too strong, we pour into his foup a little vinegar, or inftead of that, some juice of Berbery (fuccus berberum) in cafe he has too great a loofeness at that time. The fever is in general too high with us in Sweden during the disease, and therefore it is not adviseable to give the patients either broths, eggs, or wine.

It is indifpenfably neceffary to drink plentifully during the fmall-pox, and chiefly in the first period. The patient

G 3

# DISEASES OF CHILDREN,

patient ought to drink frequently, and but little at a The nurfe or waiter is not to ftand till the fick time. asks him for the drink; for he will not feel any thirst if he should be a little 'delirious. He does not chuse to drink if he has pustules in the throat, because it causes pains in fwallowing: nor need we afk the patient if he chufes to drink, but we ought to carry the tea-cup or glass to his mouth as often as we judge it necessary, during the time he is awake ; a barley-water (aqua hordeata,) mixed with a fourth part of milk, is a very falutary drink in the fmall-pox. Whey mixed with an equal portion of boiled water is very palatable, and quenches the thirst: fresh and strained butter-milk is likewife very good; alfo tea with a little milk in it, or tea with citron marmalade. One may likewife prepare a very palatable and refreshing drink of preferved red currants, on pouring on them boiling hot water, and after it is a little cooled we may add a little rhenish wine to it. Breferved Norlandic berries, in the fame manner prepared, give also a very pleafant drink, which especially is applicable on the 4th, 5th and 6th day. Barley ptifans, in which has been diffolved fome gelly, will make a cooling drink likewife; as alfo panada with the juice of limes and old hock; but nothing is fo refreshing, and quenches the thirst sooner, than a well prepared drink of cranberries, which therefore ought to be had in the fhops.

The five first forts of these drinks are chiefly the most useful in the small-pox, especially when the fever is too strong, and ought to be lowered; the latter are the most serviceable when the fever ought to be supported or increased, therefore it should be modified accordingly with wine. Those who are affected with pusseling the throat cannot bear any acidulated food or drink, much less any thing sour; the throat grows thereby worse and hoarser.

As for the cure itfelf in the first period, we must endeavour to effect it, I. By taking care that the fever pe moderate. 2. That the small-pox do not break out till towards or on the fourth day. 3. That as few puscules as possible may break out in the face, nose and throat, and none in the eyes. 4. To prevent cangerous accidents.

重.

36

If

# AND THEIR REMEDIES.

If the fever be too ftrong we abate it : 1. By bleeding, which ought to be performed, a.) If the patient has too much blood ; if we know him to be plethoric ; if he has for a long time had a good appetite, together with a found fleep and little exercise; if he has used nourishing food, beer and wine; if he has not been weakened by any evacuation; if his pulse is high and strong, the veins distended, and the face red, but especially the lips, gums, the infide of the nose, eyelids, the corners and the whites of the eye : b.) If the patient be young, of a strong complexion, and has been used to have inflammatory fevers : c.) If at this time many in the neighbourhood are affected with inflammatory fevers, or fuch in which bleeding has been found beneficial: d.) If severe cold or dryness, or north wind has been prevalent: e.) If the fever is very violent, attended with head-ach, pain in the loins and the whole body, an anxiety, figns of imminent delirium, swelling in the throat or some inflammation. The fever is violent if the pulse be quick, hard and ftrong; if a strong pulsation is felt on the temples, the patient being very hot, and unwilling to lie down; if the breath be fhort and laborious, the urine red, the tongue dry, with a great thirst\*. The figns of an imminent delirium are a strong throbbing of the ar-teries on the temples, a severe head-ach, restless, and the white of the eyes turned red and inflamed. When the patient is found under fuch circumstances, he ought without hefitation to be bled : and that not once but feveral times till the fever is abated to a moderate

\* Neverthelefs the bleeding ought not to be immoderate, in order that the fame thing may not arife from thence, as happened to the *Italian* phyficians, who on inoculating a child 11 years of age, drew off fo much blood during the preparation, as alfo after the fever came on, that the fever abated, and only a fingle puftule broke out in the child's face : but as foon as the child had recovered a little ftrength after this wafting of blood, the variolous fever returned, and a great number of pocks broke out; the cure proved however fuccefsful. See *Abhandl. de Naturforfch. Gefelfch* in *Zurich*, VOL. III. p. 175.

or

or due height. If he is too averfe to bleeding, or is too fat, fo that it cannot be performed without difficulty, we may then apply the cupping glass in the nape of the neck, and on the calf of the leg, and thereby nearly gain the fame point, and befides that, a great number of puftules are by that means derived from the face and throat. We ought not to bleed a patient who labours under contrary circumstances; therefore no blood ought to be drawn from one that has had a weak and pale countenance, or has a weak and low pulfe, and the urine colourles, the thirst and pains but little, and the droufiness great; or if he is affected with pains in the flomach, faintings, and a dejected mind. The fmall-pox that fuch a perfon gets, will neither rife nor ripen, therefore he has rather occasion for things that will raife his pulfe and increase the fever. than fuch as make them fink lower.

Children are commonly weak and fooner lofe their ftrength; grow alfo in proportion a great deal; confequently a great part of their food is employed to the increase of their body. For that reason I would rather not recommend any bleeding for them, unless there be the more obvious necessfity for it, and that we apprehend convulsions; especially as nature of her own accord causes commonly a bleeding at the nose.

2. With remedies which well cleanfe the flomach and bowels\*. As foon as the bleeding is performed, a clyfter ought to be injected; that may be prepared of tepid water, a little oil of olives, honey and faltpetre. Such an injection fhould be repeated every day, till near the time we fuppofe the puffules will break out, unlefs on a day we have thought proper to order a purge. That is generally neceffary, chiefly in cafe the patient before has had a good appetite, ufed to good chear, and but little evacuation. Chiefly if the flomach at the fame time be full and diffended, rumbling wind felt in the belly, and the pains in the loins are violent +: a proper purge for a child is the rhubarb elixir

+ That a concurring diarrhœa can retard the eruption of the imall-pox, may be feen from an inftance related in the above-

<sup>\*</sup> See V. Haller's Elem. Phyfiol. vii. p. 179.

## AND THEIR REMEDIES.

elixir prepared with wine (Tinctura Rhei dulcis Edinb. or clixir falutis Edinb.) made with wine. The dofe is nearly a spoonful for a child three years of age; or we may take half a drachm of rhubarb cut in fine pieces, a few grains of cochineal, and four raifins likewife cut; on this we pour three tea-cups full of boiling water in a tea-pot, which is to be put on hot ashes during the night, filtered and mixed with a tea-spoonful of cinnamon water, of this the child must drink two tea-cups full immediately, and the remainder an hour But these purges are too flow in their operaafter. tion; and it is of the greatest importance to abate the fever to a moderate and gentle degree in the first period; for scarce one patient dies, of those who then have the fever moderate. The above remedies I have proposed are good, but not always sufficient, especially if the contagion of the fmall-pox is connected with a putrid fever. Nothing moderates the violence of the fever fo effectually as purges, which operate quickly and freely, and are given before the eruption. The English have first taught us this, and our own experience has confirmed their affertion. When fuch a remedy has quickly made its operation, and with an evacuation to fome purpofe, we have found that head-ach, delirium, swelled and red face, sleepiness or droufiness nearly refembling lethargy, and all bad fymptoms at once have been carried away; and that in the fmall-pox. both from natural infection and by the incifion. If the fever has not abated fufficiently after the first dofe, we have given another if the time allowed it. Some of my friends among the phyficians in Stockholm, have alio by letters to me confirmed the fame : the purge they had prefcribed, was commonly a powder prepared of cremor tartari three drachms, root of jalap half a diachm, and tartarus emeticus one, or one and a half,

above-mentioned Transactions of Zurich, Vol. III. p. 174. When the diarrhœa had ceased, and the child recovered strength again, the variolous fever returned, the pussules broke out, and the event was prosperous. This happened by an inoculation, and may likewise happen by a natural infection.

oŗ

# DISEASES OF CHILDREN,

or two grains, according to the age of the child, and other circumstances. This they divided into fix parts, and gave one part every hour till it began to operate; professor Bergius ordered, with the same success, a powder made of tartarus emeticus three grains, and cremor tartari three drachms, well rubbed together, and divided in eight parts, to be taken as the former. We have learned from the French physicians, that tartarus emeticus does not occasion a vomiting, but purges if we mix it with fome falt, and rub it very fine. Emetics are feldom wanted in the fmall-pox \*, for the fick And in order to facilipuke enough without them. tate the vomiting, we give them to drink fome warm water after each reaching, till it is at last thrown up again untinged, and we may then with reason think the stomach cleanfed.

3. With cooling food and drink, and fuch as above was mentioned. . 4. With cooling remedies. For instance, we may prepare small powders of fix grains of purified nitre, and 30 grains of morfulæ citri, and give one of them every hour, or hour and a half; or cremor tartari 10 grains, mixed with an equal portion of fugar. If the child has rather a loofenefs, we must order purified fal ammoniacum instead of nitre, but the powder should then be taken in wafers, in order to avoid the tafte. One ought to be cautious in regard to the nitrous medicines, and not to use them too freely, especially with weak and sensible children, who will be injured by them in their ftomach. In cafe we fhould prefer a draught, it may be prepared, for instance, of two quarts of boiled water, which afterwards has been cooled, mixing with it three ounces of good vinegar, three ounces of fyrup of rafberries, and as much

\* They are however required, when nature of her own ac<sub>τ</sub> cord does not excite vomiting, although the child fhould be troubled with flime: if it has a fnoring in the breaft, has a pale and funken countenance, and is fubject to convultions, alfo when the fpots of the fmall-pox cannot break out and rife in confequence of this weaknefs and dullnefs, but feem as if they were confined under the fkin, and the child lies as in a lethargy.

90

ef

of pearl-barley foup; this we give to drink freely and frequently, a tea-cup full at a time.

5. By lefs heat in the room. 6. By giving him a thinner covering : and 7. By often changing his bed, fo that the patient is carried from one bed to another, and does not return to his former one before the bed cloaths have had time to cool. 8. By prevailing on him to get out of his bed as much as possible, which will prove very falutary to him.

If the fever fhould be too flight, which is however feldom the cafe during this period, bleeding ought then to be omitted, but ftools muft be procured for all that, as is above obferved. We increase the fever; 1. By heating the chamber more. 2. By a thicker and warmer covering. 3. By food and drink, with a little wine to it; a whey of wine will be very much to the purpofe in this cafe. 4. By a paste or poultice made of acrid mustard-feeds with vinegar, and applied to the foles of the feet, or on each calf of the leg; this must be removed as foon as the fkin grows red and fpotted.

We have no method, with any fafety, to prevent the breaking out of the puftules till on the fourth day, but in abstaining from the use of expellent remedies on the first three days; for instance, as musk, camphire, flowers of fulphur, &c. and taking care that the room be kept rather cool. We likewise prevail on the patient to keep out of bed, or at least not to lie under the cloaths.

We endeavour to fecure the face, eyes, nofe and throat from being overrun with pocks; I. By bleeding or applying leecnes, when circumftances will allow the use of these remedies, as has been above observed. 2. By fcratching the fkin in feveral places without piercing it; this may be effected on the arms and legs with a pin or the point of a lancet; fee more of this in the next Chapter on Inoculation. When the extremities and the furface of the body are in this manner irritated, the blood will flow in a greater quantity to those parts : and the greater number of pustules. and fuppuration we are able to raife on the arms and legs, the more are the face, eyes, nofe and neck fecured, by means of the revulfion they caufe; therefore it will answer the fame purpose, 3. to apply finapifma

# DISEASES OF CHILDREN,

finapilms on the foles of the feet, or on the calf of the legs, or on the arms; this will be proved by the instance I am going to give in the Chapter of Inoculation. 4. With the fame intention we foment the laft mentioned places with flannels or linen foaked in a warm decoction of carrots and milk, afterwards fqueezed and applied, taking care to change them as often as they begin to cool. We find how feldom the pocks break out on the foles of the feet and on the belly, because the skin in the first place is generally hard, and in the latter very rough. For the fame reafon we, 5. ought to keep the under parts of the body warmer than the upper; and 6. we fhould fhave the head, by which means it is kept cooler and perfpires better. We may as well do this at first, as the hair otherwise sticks fast together with the puftules, fo that it will be necessary to cut it off sooner or later.

We endeavour befides to guard the eyes, by means of a linen compress, on which some camphire has been rubbed, fastening it to the night cap, so that it hangs loosely over and covers the eyes.

As the fcars do not occasion any deformity of the face, provided the nofe is not hurt, therefore one of our principal endeavours should be to preferve that part. In order to effect this, apply on it small linen rags foaked with a little camphire spirit, or balfamum embryonum; but one muss however allow the strongest part of this first to perspire away; emplastrum de ranis cum mercurio will answer the same purpose, if it is thinly spread on a piece of linen, and applied to the nose \*. In case a number of pussues have broken out in the nostrils, and cause the patient to breathe through the open mouth, it is of service to put small linen rolls in the nose that have been soaked in milk, taking care that the broader end of them are always dry.

It is a vulgar custom with us to stitch black wool to a bandage, and befinearing it with theriaca, tie it

\* I find that Dr. Sulzer has been pleafed to follow this my advice; and that it has proved fuccefsful. So that the child got no puffules on the nofe. See the Transact. of Zurich, vol. III. p. 53.

round

# AND THEIR REMEDIES.

round the neck in order to prevent the pustules fettling in the throat. This seems to do neither good nor harm; it will be more beneficial to apply leeches to the nape of the neck of the patient, and perfuade him to gargle himfelf freely and frequently with a water prepared as follows; take a drachm of camphire, pour on it a few drops of (liquor anodynus mineralis Hoffmanni) Dr. Hoffman's mineral anodine drops, and rub it in a marble mortar; add to this four drachms of fugar, and rub it again, fo that all be well mixed; pour gradually on this two pints of hot water, and ftrain it directly. This to be preferved in a bottle well corked : one may use of this half a tea-cup full at a time; at each time we add to it a few drops of the above-mentioned liquor anod. min. In cafe the puffules are already broke out in the throat, our province must then be to bring them foon to maturity and desquamation, which can best be obtained by a frequent gargling with warm milk or thin oat-gruel foup.

The trouble fome accidents or fymptoms which ufually attend in the first period, are vomiting, delirium, loofenefs, hæmorrhage of the nofe, and convultions. As the vomiting cleanfes the ftomach, it fhould be promoted with milk-warm water; if it is too violent we must apply to the stomach bags with mint, (mentha crifpå) with some faffron put to it, or we boil these bags in rhenish wine, and squeezing them well out, apply them moderatly heated to the ftomach; or we may boil a poultice of leavened bread and mint, together with vinegar or rhenish wine, and putting it into a linen bag, apply it to the ftomach; the vomiting ceases of its own accord as foon the eruption is quite compleat. A delirium is not dangerous in the first period, as it is owing only to a rapid circulation of the blood; we oppofe to it the fame remedies by which the fever was to be moderated. A clifter injected, and leeches applied in the nape of the neck, often prove fufficient. In children it generally ceafes by a bleeding of the nofe,. which commonly is portended by an itching or tickling of the nofe, or by an excruciating or fhooting pain in either of the fides, which comes and goes off haftily.

Too great a loofeness may be prevented, by giving rhubarb in the very beginning of the disease, in the

manner

i,

94

manner as above was obferved. A diarrhœa is not hurtful the first days; but it ought to be stopped in cafe it should continue till the time of eruption; we may stop it by a convenient diet, and an emulsio arabica prepared of three drachms of gummi arabicum boiled in two pints of water, and afterwards mixed with an ounce of sweet almonds blanched and pounded; likewife by a clyster prepared of milk, a little theriaca and white starch; or of lime water, a little diascordium and balsamus Locatelli beaten together with the yolk of an egg. Tender infants are affected with some looseness during the whole course of the severer kind of small-pox, and this looseness proves generally to their advantage.

The fame is the cafe with the bleeding of the nofe, when it is moderate \*: head-ach and delirium are thereby relieved, and the fever itfelf diminished. The patient ought to bleed but in a tea-cup, plate, or veffel, in order that one may judge of the quantity, whether it be moderate or not; if it should be too copious, which we likewife judge from a greater lowering or finking of the pulse, we stop it by *fungus* cut in form of a long cone, and put in the nose: or we beat the white of an egg and alum together, spread it on a tent, and putting it up into the nose, leave it there till it falls out of its own accord.

Convultions commonly portend a favourable fmallpox; when they come on, it happens either on the first night of the fever, or more commonly a little before the eruption; we prevent them by bleeding; but may relieve them by a clyster of milk, oil, and fugar; and by giving the child as foon as it is able to fwallow, a powder of two or three grains of music previously rubbed with 10 or 12 grains of fugar: a gentle vomit will have a more certain effect on this occafion  $\dagger$ .

Thê

\* See V. Haller's Elem. Physiol. V. p. 150.

+ A child eight months of age was inoculated in the year 1770, in the fpring, and got convultions; had a hollow fnoring in the breast, its hue was pale, the body coolifh, and its pulse quick. The child could not recover its natural warmth

## AND THEIR REMEDIES.

## The Second Period.

During these days, our efforts should be to promote a good eruption of the puscules, that they rife full, and become pointed; there is however no occasion for any expellent remedies, if we find that the puscules break out gradually, grow elevated and broader, that the pulse is moderately high and strong, and not too quick, but beats for instance fomething more than 120 strokes in a minute in a child, and about 96 strokes in a full grown person; all that is then requisite for the patient, is to let him drink freely, in order that his blood may be supplied with a sufficiency to fill the puscules.

But in cafe the puftules will not break out freely, and still lefs rife and fill, the vomiting continues, the pulse is low, weak, and quick at the same time; then we ought to give our patient one or two spoonfuls of. wine or mead, or we let him drink a whey of wine. Now it is likewife proper to give him fmall powders, prepared of a few grains of camphire, one grain of extract of faffron, and 30 grains of preferved citron peel (morfulæ citri): or a camphire emulfion made of half. a drachm of camphire, rubbed with fix almonds blanched and pounded, and then mixed with half a pint of aqua florum ulmariæ, and two drachms of fugar; a teacup full of this is the dofe at a time; or we may prefcribe powders of musk and sugar as above-mentioned, ordering some tea of ulmaria (flores ulmariæ) to be drank after it; but, as we have observed, this is seldom want-When I have been affured of the child's beed. ing well and properly nurfed, the fteam of warm milk has been directed to the face; by which means I have found the pustules begin to rife immediately : I have

warmth or ufual colour in the face, before it got a few pukings by *ipecacuanha*, mixed with *oxymel fchilliticum*; this at first evacuated a quantity of flime, and afterwards purged gently. Perhaps the *tartarus emeticus* would be more proper on fuch occasions, as it afterwards gives the humors a greater tendency towards the skin, than the *ipecacuanha*. formefometimes applied finapifms to the calfs of the legs with great advantage.

All this fucceeds fometimes exceedingly well; the pustules break out, and they rife likewife; but it often happens that they of a fudden fubfide again; turning either pale, or containing a matter which does not grow yellow or ripen, but turns black and ftinking, furrounded with petechial fpots; therefore as foon as I find that the puftules are backward and flow in their breaking out and rifing during this period, I immediately begin to give the jefuits bark, especially if I know that the prefent contagion of the fmall-pox has been malignant, and that the patient is of a weak constitution; and I continue this remedy during the whole course of the disease, giving it oftener, or in greater dofes, when the pulfe is weak, and the red colour round the puftules is lefs; but in cafe the pulfe is quick, and the above-mentioned rednefs greater, the dofes of the bark are leffened accordingly, or given at longer intervals. This method has been followed by many Swedish physicians, and attended with great fucces; and has been before us used by the English physicians, Morton, Mead, Monro, Wall, Huxham and others : neverthelefs, it is a difficult tafk to make the bark palatable, fo that children can take it. How to gain this point, shall be afterwards shewn in the Chapter on the Ague; it would be very eafy to mix wet bark up in wafers, provided children could fwallow fuch lumps; the tafte of bark will likewife be made tolerable, by beating it with bitter almonds; powder of bark may also be tolerably well swallowed in the common almond milk; the bark mixed with the bacc. Norlandic. and fyrup of the fame may be made into a palatable electuary, which even for the fake of the Norlandic berries alone, is now very proper and falutary. The following composition is also very good : take the confection of the lemon peel one ounce and a half, and an equal portion of orange peels; beat them well together in a mortar, adding gradually during the time aqua ulmariæ half a pint, and aqua aurantiorum a gill; this is to be strained and mixed with three drachms of powdered bark, and fyrupus aurantiorum or syrupus baccarum Norlandic. about two ounces; or we may

may make a tolerably palatable drink of two drachms of extract of bark, diffolved in 10 ounces of aqua ceraforum; adding to this three ounces of fyrupus citri e toto; the dofe is a spoonful at a time.

As the bark is a very falutary and bleffed remedy, it is of importance always to try before hand, whether it be genuine of adulterated. This may be done in the following manner: boil a little powder of bark in water, and pour it directly into a glafs bottle; if the decoction appear of a red colour while it is ftill warm; and pale after it has cooled, one may depend on its goodnefs; otherwife not.

It happens likewife frequently that the pocks cannot break out; on account of the fever's being too violent and fevere: Those who are of a strong constitution, have firm fibres, and thick blood, the cruor in it being prevalent; are subject to this difficulty; we ought then to use those remedies which diminish the fever, and which are the fame as above enumerated at No. 1, 2; 3, 4, &c. at the fame time foftening the fkin on the arms, hands, feet, and legs with fomentations, as alfo has been mentioned before; powders of camphire may be likewife now made use of, but prepared of seven grains of nitre, three grains of camphire, and 30 grains of morfulæ citri. If the pain in the loins still continues and is violent, that may also retard the eruption ; therefore in that cafe; one must apply a warm poultice of groats wrapt up in cloths; on the back of the patient, and give him either the fyrupus e meconio Edinburg. or the Elixir paregor. Lond. and at the fame time, one of the above remedies which will promote the eruption; the dofe of the elixir for a child, is from five to 20 drops in fome fyrup, with which it ought to be well mixed:

Should the patient be delirious, although the eruption is tolerably well compleated, we ought immediately to apply the *finapifins* on the feet, and leeches to the nape of the neck. We find that the lungs are juft beginning to inflame, when the patient complains of a load on his breaft, hawks up blood, the fever continues, the breathing grows difficult, and is found to be hot when one holds the hand before his nofe and M

98

mouth; in that cafe he ought immediately to be bled. See more of this in the Chapter on Meafles.

In cafe the fick is affected with a pleurify, we employ the fame remedies, and the fide muft be fomented with *oleum camphoratum Edinb*. A pain in the fide, which comes on, and goes off of a fudden, commonly announces an impendent bleeding of the nofe. If too great a loofenefs, or a true dyfentery fhould concur in this period, we muft immediately employ the remedies, as above recommended for the loofenefs, and at the fame time ufe the powders of camphire, prepared without nitre, but mixed with the eighth or fourth part of a grain of *opium*, according to the age of the patient.

#### The Third Period.

In this period the puftules begin to flink, itch, and ripen \*. What was observed at the beginning of the fecond period, likewife holds good here : if nature herfelf is sufficient, she will want no other affistance than plentiful drinking; but if the pulse be too weak, or too ftrong, we may use the remedies above recommended, for either raifing or lowering it. No fuppurative fever will enfue when the small-pox is very favourable; but if the difease be severe, the fick will towards night grow affected with an uneafinefs, and become reftlefs, fo that they lie toffing themfelves from one fide of the bed to the other. In fuch a cafe it is cuftomary to give a child a little of the syrupus e Meconio; but it is more adviseable to leave that alone, and ráther give it fome of the drink, as mentioned at No. 4. or according to the advice of the worthy Dr. . Tiffot, (in his Letters to Baron Van Haller), let the child take the following mixture :

> R. Spir. Vitrioli, 3 ß. Syrupus Violar. 3iij. M. Dr. S. Cooling mixture.

\* That the pus can burn, is an observation made by V. Haller, Opusc. min. iii. p. 356.

The

The dofe is ten drops at a time, taken in a tea-cupful of pearl-barley water, and repeated more or lefs frequently in a day. Now in order to prevent the patient from fcratching himfelf, it is neceffary to tie his hands, and to have a perfon attending at his bed, ftreaking over the puftules in his face with a quill continually and gently.

If the fmall-pox be malignant, then the fuppurative fever (*febris fuppuratoria variolarum*) will begin with a quick pulfe, heat, thirft, uncafinefs, and want of fleep \*. Sometimes it comes on fuddenly, and with fuch a violence, that before we know any thing about the matter, we find the patient in a fevere *delirium*, with a fwelled throat; or an inflammation in the breaft, or pleurify. The following are the caufes of this fever.

1. The nerves of the skin are irritated partly by means of the swelling in the face and whole body, which causes a tension in the skin, and partly by the formation of the *pus* in the pussules and their distention.

2. The natural and usual perspiration is intercepted by the skin being overrun with pussules. Suppose only one third of the skin to be overrun and crowded with pussules; nevertheless nine ounces of perspirable matter will by that means be retained at least for each day, which will always occasion a fever by its acrimony, unless it is carried off some other ways.

Sometimes it will likewife happen, that the puftules fubfide; and that a great part of the *pus* is abforbed into the blood, which increafes the fever a great deal; but, as that belongs chiefly to the fourth period, it fhall be mentioned there.

This fever will prove more fevere and dangerous, in proportion as the conftitution of the fick is more fenfible, and the number of the puffules greater, and malignant, and the blood has been lefs diluted in the

\* Those who have a nice, or subtil smell, are able thereby to know, whether this fever will break out the next day.

first

first periods with a proper and fufficient drink; accordingly, it will be of the greatest importance to prevent it, and to procure the patient a good nurse. The first cause of this fever may be diminished, or entirely removed, by copious drinking, and by somenting the extremities, as I have before prescribed : if the pussules are very painful, we may then give the child a little sympus & Meconio.

The fecond caufe of this fever, we endeavour likewife to remove, partly by copious drinking, for the acrimony is blunted by being diluted; partly by procuring it another outlet; for inftance, through those pores of the skin, where there are no pustules, and by taking powders of camphire. I have many times observed the fick brought into a fweat at those places \*; and likewife to have had fome reft and fleep after each powder, during which time the puftules have rifen, and confequently been more filled with a part of this matter; therefore it is very beneficial, to open at least the largest and most coherent pustules, by means of a pin, lancet, or the sciffars, in order to discharge a great part of the corrofive variolous matter; but this must be repeated several times in a day, as they foon grow together again. The matter which runs out at each opening, ought to be wiped off by a fine spunge, dipped in milk-warm water. The perfpirable matter may get another iffue by a more copious falivation, of which we shall afterwards learn, how it may be promoted; also by a more copious discharge of urine, which we may encourage by drinking freely, especially if small doses of spiritus Mindereri are put into the drink, or we take half a drachm, or a drachm of this fpirit in oxymel scilliticum, or by the powders of cremor Tartari, as before-mentioned. Sometimes this perfpirable matter goes off by frequent ftools, that often to the advantage of the patient, and which gave occasion to the learned Dr. Friend to prefcribe purges. They ought

\* B. V. Haller is perhaps the first, who brought camphire into use in this difease. With how great success he imployed this remedy during a malignant contagion, may be read in his Op. min. iii. p. 350.

to

to be given as foon as the greater part of the puftules in the face have begun to dry. We have no other resource than that, in case the falivation ceases, the fwelling in the face difappears, without being transferred to the hands and fingers, and the discharge of urine decreases. It is however safest, first, to inject a clyster, (which ought to be done every day, during the whole course of the disease, in case nature of her own accord does not procure stools), and after that has operated, we must attentively observe, whether a low, quick and trembling pulse rifes, and is filled : if the uneafinefs and the heat decreafes, the fhort and difficult breathing leffens, we may then, in fuch case, with safety give a gentle purge of diacassia Edinb. diffolved in whey; or we may prepare a drink of manna and tamarinds, haftily boiled together in water, and being strained, made palatable with a little fyrup of raspberries; but we ought not to neglect giving the patient a cordial during the operation. Such a one may be prepared, of cranberry water, four ounces; cherry wine, two ounces; 15 drops of the liquor anodyn. Hoffm. and two or three drachms of fyrup of raspberries.

If the fever fhould be too violent, we are obliged likewife to bleed in this period, tho' it will hardly be wanted, provided we drink copiously of the just now mentioned cooling-mixture.

I here repeat what has been faid in the fecond period, that these remedies prove often exceedingly good, but feldom succeed in a very malignant small-pox; therefore I now adhere to the use of bark, and wholoever prefcribes it according to the advice I have before given, will find that this remedy often works miracles: and that he will have no occasion for other remedies.

It was mentioned as a favourable fign, when the face continues swelled till the eleventh day; but in confequence of that, the eye-lids will fwell and flick together, fo that the patients are unable to fee during that time. A great number of phyficians do not meddle at all with this; but I think it fafer to open the eyes once a day, in order that we may fee if they fuffer in any manner. They may most eafily be

IOI

be opened by being licked with the point of the tongue. If nobody can be perfuaded to do this, we may dip a piece of foft linen in milk mixed with water, fqueezing it out, and applying it moderately warm to the eye-lids, fo long till by the fingers we are able cautioufly to divide them.

. I promifed to fay fomething about the fpitting, which is an evacuation indifpenfably neceffary in a malignant small-pox, portending much evil when it . flows with difficulty, or ceafes too early. Spitting is feldom observed in children, but older persons begin to fpit already on the fifth or fixth; nay fometimes on the fourth day, from the first feifure. The fooner. it begins, the worfe the difeafe will prove. It flows very eafy in the beginning, being then thin, and very copious; but when the tenth and eleventh day comes on, it will grow thick and vifcid, is performed with great difficulty, fo as to be even fuffocating. This is prevented and relieved with a copious and warm drink, by frequent gargling, and injections by fyringes: as a gargarism may be used the decoctum pectorale Lond. taking a pint of that, and mixing it with one ounce of acetum scilliticum, and one ounce of mel rofarum; or decoction of carrots, mixt with a little fyrup of violets; or one may take radix altheæ, (marsh mallow root) two ounces, four figs; boil them with three pints of water, till the half is confumed; or boil bruised flax-seeds, half an ounce, in a pint of water, till two thirds are remaining, that being ftrained, add a little clarified honey. The fame ferves also for fyringing, which promotes the ripening and fcaling of the pultules in the throat; but nothing promotes the spitting better, and relieves the throat, than drinking warm milk with a little fugar to it; fometimes by itfelf, fometimes mixed with tea, barley water, or oatgruel.

The patient ought not to lay on his back, neither in this period nor in the following, but turn now on the one, now on the other fide, in order to prevent the *faliva* from falling down in the throat; therefore one must likewise put a fost and warm napkin under that cheek he leans on, and shift it as often as it is necessary.

The

### The Fourth Period.

If all has fucceeded favourably, and in its order, nothing will be wanted in the fourth period, but good nurfing and drink; efpecially if the fmall pox is benign, the fpitting and breathing performed eafily, the puftules ripen and dry, the fwelling which has hitherto been in the face, is transferred to the hands and fingers, and afterwards to the feet, the fleep is likewife good, together with a beginning of appetite.

But if the small-pox is of a malignant kind, a new fever will then arife from the pus in the pustules, which is not wholly perfpired through the scales, but . partly abforbed into the blood; this fever will likewife arife from the great quantity of foul substance collected in the ftomach and bowels, when the patient has been coftive during the course of the difease; therefore that being taken up, and carried into the blood by the lacteal and abforbent veffels in those parts, it must necessarily cause a fever by irritating, and that of the putrid kind. This will not go off till the above-mentioned pus is wholly carried out of the body; nay if it be transferred to the brain, there caufing a difficult delirium, or a profound fleep; or to the lungs, there caufing a fevere afthma, an inevitable death will enfue : if it is transferred to the eyes or ears, the fight or hearing will be loft : it is therefore of great importance to prevent this fever if possible. The bark, together with a strengthening diet, added to those remedies which cleanse the body from the pus, are the most effectual for that purpose; I mean such as will raife the puftules and promote the fpitting, together with a copious discharge of urine. Gentle purges are likewife conducive to it, when ufed with the precautions I advifed in the third period. Here it is also of some fervice to foment the arms, hands, legs, and feet, and to apply a finapifm, in cafe the pulse is low and weak.

It often happens, that the *pus* is thrown to fome place on the furface of the body, there forming a tumour, fometimes attended with pain, but commonly indolent: if this matter gets an iffue, and is not H 4 abforbed abforbed again, the patient will be then quite cured. We ought therefore not to neglect to look for this: if no tumour is to be feen, we order the patient to cough, inquiring if during the time he fome where feels it: if there be found the leaft fign of fwelling, apply on it directly a poultice boiled, of milk, wheat, flour, a baked onion, and a little faffron; as foon as we obferve any matter under it, open it with a lancet.

As foon as the pultules dry in the face \*, we ought to begin to anoint the crufts in the fame order as they are formed, but not earlier. I have always employed a foup of groats for that purpofe, with a little fugar in it, and an oil prepared by fhaking one ounce of oil of almonds or olives with a drachm of *oleum Tartari*. Thefe two remedies ought to be brufhed on the crufts alternatively, fo that when the first has been employed once, the other is to be used next.

Sometimes I have used veal-broth, sometimes warm milk, in which a fine spunge has been dipped, in order to streak the face over frequently. Some recommend to anoint the crusts with a quill dipped in a mixture of chalk and cream.

The patient having at laft gone through the fmallpox, and the crufts fcaling; it is highly neceffary that he lhould be purged fix or feven times, at the interval of four days between each purging. The *electuarium lenitivum Lond.* may be ufed for that purpofe, about two, three, or four drachms, according to the age of the child. For, if this be neglected, the child may eafily get affected with weak lungs, bad eyes, fcabs or boils. It is not probable, that thofe who have once had the true fmall-pox, can receive the infection a fecond time +. I have often heard it mentioned, but as yet

\* Some pretend, that the fcars of the fmall-pox on the Negroes are white; they are fomething paler in the beginning, but foon grow black again: the fame is the cafe with the fcar after inoculation, which I have feen in two of them.

† The difeafe called Framboefia Guineensis, likewise affects a person no more than once. See Sauvages Nosol. iii, ii. p. 425.

3

never

### AND THEIR REMEDIES.

never found any inftance of it well confirmed, nor, to my knowledge, any other experienced phyfician in this kingdom. One may indeed get the chryftalline, or watery kind, but never the true fmall-pox. Some perfons, who have had a very gentle fmall-pox, or only one dingle puftule, have been apprehenfive of getting the difeafe again, but yet were always fafe, tho' they converfed with perfons fick of the malignant kinds. Some have chosen to be inoculated for greater fecurity's fake; but the infection never would take, provided they had had the difeafe before, either by a natural contagion, or by inoculation.

When the contagion of the fmall-pox begins in a place, and the queftion is proposed, from whence they first got the contagion? The answer is obvious, that this infection has been circulating from one place to another, either by people or baggage, ever fince the first introduction of the disease into Europe.

When the fmall-pox is conveyed to a place, it will not leave off, as long as there remains any body fufceptible of the contagion, unlefs those who dread the difease most take the greatest care that it do not reach them or their children : that the winter's cold is not able to stop the infection, I found very plainly at Upfal in the year 1743.

There is no inevitable neceffity, that every individual perfon must have this difease; how great a part of mankind is there, who have lived in America, without ever having had the infection? For the small-pox was first conveyed there from Europe, in the year 1492. Nor was it ever in Greepland, till it was conveyed there from Denmark, in the year 1733. Phyficians have found, that among a hundred perfons inoculated for the fmall-pox, there are commonly about five on whom the contagion does not take, and who confequently are sure not to get the difease; therefore among a hundred persons, there are 95 who have in their blood a disposition susceptible of the small-pox, and which never can break out, unless by infection. The same is the case with the plague; it never arises in us of its own accord, but is conveyed from infected countries, and never can attack those who fly in time.

Whether

Whether there be any one among us, who never has had, or never gets the fmall-pox, is very difficult to afcertain. If the general rule be certain, that the inoculation does not take in five among a hundred, it is fure enough, that these will not get the disease. But it remains nevertheless a doubt and an uncertainty, whether they have not had them in their infancy, and of fo gentle a kind, that the parents have looked upon the eruption as pimples. This puts me in mind of a young lady, who had the disease so favourably, that her parents did not fuspect it to be the small-pox, but took her in their coach, on going to use the mineral water at Sätra. I met them by chance, and the journey was deferred till the difeafe was over. Befides we know feveral children to have had the fmall-pox at their births; from whence it follows, that a part may have had them in their mother's womb. Of feveral fuch inftances, I will here only relate one, which happened about the year 1756. A child had crufts and fcars of the fmall-pox on its body, when it was brought into the world; for the eldeft fon had the fmall-pox a little before this was born : all the other children got the fmall-pox fix years after that, except this, who certainly had had the infection already in its mother's womb \*. We have likewife inftances of those, who first received the infection when they were old. A man at Upfal got the small-pox after his 50th year. Nevertheless the event was fuccessful. A lady in England died of the small-pox in her 72d year. Another was infected in her 73d year, and with that remarkable circumstance, that the disease was first benign, but afterwards on the 15th day proved fevere, and the puftules became confluent. In the parish of Torsong, and village of Sylla, in the great province of Kopparberg, a woman got the fmall-pox after having paft her

\* Phyficians have written down feveral inftances. See Mead, de Variolis, p. 66, 67. Fulleri Exanth. p. 192. Neverthelefs, it does not always happen that a mother, who has the fmall-pox, infects her fatus. See Kirkpatrick, c. i. p. 21.

80th

Both year; fhe had a great number of puftules, but happily recovered. See the news-paper of the provinces, for the year 1770, No. 35.

We know very well, that fear cannot be the caufe of the plague, as children have been infected by it foon after their birth; the fame is to be underftood of the fmall-pox; for a *fœtus*, when ftill in the womb, or foon after being brought into the world, is frequently infected, before it knows either what fear or fmallpox fignifies. However the infection takes more eafily on those who dread the disease; for fear debilitates the nerves and heart, and makes the circulation of the blood flower, which causes the absorbent vessels to be more dilated, and to admit the infection the more eafily.

The small-pox carries off yearly the tenth part of Swedisch children. It is remarkable, that notwithstanding the male children are more numerous, nevertheless a greater number of the female fex die of the small-pox. On the contrary, the other diseases of children kill more boys than girls, so that both fexes are already at the fifth year of an equal number; but after the 15th, the female fex is found by far more numerous. See the Transactions of the Royal Academy of Sciences at Stockholm, for the Year 1755, p. 247.

In the fmall-pox, from the natural contagion, I find that Baron *Dimfdale* has likewife ufed, with fuccefs, his new method of treating this difeafe the fame as in inoculation. Some cafes of this may be feen in his book, of a *New Method of Inoculating*, &c. and which is now translated into the *Swedifb* language, by *Archiater Beck*.

In the Transactions of Zurich, vol. ii. p. 386-414. is to be read a well kept journal of a cure of two children, ill of a fevere small-pox, performed by Dr. Zimmerman, with affiduity and good judgment \*.

\* Professor Baldinger in Jena, whose merits in physic are well known, has printed this chapter separately, together with that of Dr. Tiffot, on the same subject. He has thereby conferred much honour on me; but at the same time discovered my inferior talents, by placing me together with a man of such great merit.

CHAP.

# C H A P. XIII.

# On the Inoculation of the Small-pox.

THE accounts purpofely kept all over Sweden, on the mortality in certain difeafes, fhew that the fmall-pox is one of the most fatal, and confequently one of the greatest causes of the fcarcity of people, we for much complain of in this kingdom; therefore let us here confider the means and remedies, which, next to the Almighty, will enable us to endeavour, that but few perfons shall die of this difease, otherwise for lethisferous.

The finall-pox is contracted feveral ways: it would be of importance to know which is attended with the leaft danger. The fureft would be, no doubt, to avoid the contagion by flight; but the mutual connection of mankind is indifpenfable. We meet one another in fairs, in churches, and a thoufand other places. Our children lately deceased of the fmall-pox are buried in the church; we ftand and walk on their monuments; we breathe the air infected with the variolous infection, which befides is carried from one houfe to another by dogs and other animals. In that refpect, we have great reason to advance, that the fmall-pox is a difease unavoidable to the commonalty of mankind. Bleffed therefore be he who can difcover an antidote against this poison !

The late Doctor Baerhaave thought that he would be able to prepare a remedy of antimony and quickfilver, whereby the variolous miasma itself could be destroyed. Probably a few of his experiments succeeded; but repeated trials at last made him doubtful, as he, being a thorough honest man, would otherwise have made so great a discovery public.

It is probably on this foundation, that the phyficians of *Philadelphia* gave those they had inoculated, every other night, a little mercurius dulcis and antimonium diaphoreticum, and every other morning pulvis cornachini,

cornachini, and at last fulphur. auratum antimonii mixed with a little mercurius dulcis. Notwithstanding this boldness, the above physicians had the fatisfaction to find, that of 700 inoculated, only one died; see Kirkpatrick's Analysis, p. 329.

Boerhaave was likewife of opinion, that we might suffocate this difease in its infant state, or before the fmall-pox fhould break out; he looked upon the fmallpox as an inflammatory fever, and on each pustule as a boil; therefore he thought, if this inflammatory fever was cut fhort, or immediately moderated by copious bleeding, clysters, sufficient drink, baths, a cool room and refrigerant remedies, that no small boils or pustules would enfue; perhaps he himself has frequently fucceeded in this: this method was with the fame fuccefs practifed by De la Metrie, (if we may believe the affertions of this declared enemy to both religion and morals) : the honeft and fincere Dr. Cleghorn used the fame method, in hopes to fave the lives of those who were infected with a fatal smallpox, which raged in Minorca, in the year 1746 : few were thereby relieved, and no eruption enfued in three or four subjects; but notwithstanding his care in employing all that ufually proves conducive in inflam= matory fevers, the most part miserably lost their lives. The same we find of Dr. Tralles dissertatio epistolica, de methodo medendi variolis hactenus cognita, sæpe insufficiente, &c. besides, it is uncertain, whether those who are cured in this manner, can make themfelves fure of not be-- ing infected again another time; those who are cured of a pleurify can feveral times get that inflammatory fever again.

They have fucceeded better with the common people in the principality of Wales, in Saxony, and in Sweden, chiefly in the provinces of Ofler-and, Weft-Gothland, where it has been cuftomary for a long time to purchafe the fmall-pox; but as they have not understood fo well to prepare the body before the variolous matter was applied, we may find that their method of inoculation is not fufficiently fafe enough.

The old pious Doctor Lobb entered into both the opinions of Doctor Boerhaave, and thought that he had found a powerful remedy in the Æthiopsmineralis,

mineralis, which either could alter the nature of the variolous matter, or diminish this poison to such a degree, after it was already mixed with the blood, that in fine it would not be necessary to ftop at the furface of the skin, and then form pocks, but be qualified to perfpire with eafe : therefore when any contagion of a small-pox was spread, he gave those who asked his advice, of the before-mentioned æthiops mineralis, every morning and night, mixed with a little flores sulphuris, and told them afterwards to keep a good dies: he afferts, that feveral who could not avoid flaying with patients affected with the fmall-pox, were for that time preferved from the contagion by means of this remedy, and that if any one happened to be infected, he had the difease very favourable; nay, he went fo far as to think that he could, by a more free use of this same powder, quite suffocate the variolous fever in its first period, and fo far alter the infected blood, that the poifon of the small-pox should not take effect, but be partly obliged to transpire, and partly to be carried off with the urine; however he does not confirm this tale by any example.

To take of the *æthiops mineralis*, from fix, ten, to 20, or 30 grains, twice a day, according to the age of the patient, I think to be very good, but it is attended with three inconveniences. 1. That a child finds difficulty in taking it, unlefs it be mixed with honey. 2. If he who takes it is disposed to loofeness, the æthiops will intirely be carried off with the ftools, and in that cafe nothing will enter the blood, and confequently it cannot prevent the contagion, or its effect. 3. On the contrary, if any one takes it who is subject to coffiveness, he may easily, as experience has confirmed, fall into a falivation; this can however be prevented, by combining the æthiops with fome gentle laxative and a little camphire; in confequence of this, we find that the pills of Mr. Belloft are likewife a good preservative.

The late Bifhop *Berkley* enumerated, among the many qualities of tar-water, that of preferving from the fmall-pox, or at leaft rendering this difease more favourable : we are to begin with it as soon as the small-

pox

IIO

pox begins to fpread in the neighbourhood, by drinking a larger or fmaller glafs of it morning and night, according to the age of the patient, thus continuing it till we either get the fmall-pox, or till the contagion has ceafed : he pretends likewife, that it may be taken with fuccefs during the courfe of the difeafe itfelf.

This is a remedy which may always be procured, and without any expence: therefore the common people should give it to their children, who have not yet had the fmall-pox, in order to use it as above-mentioned, from the beginning of the contagion till it has ceased; it would be too tedious to quote all the cases which some Englishmen have written down, to prove this quality of the tar-water. Let it fuffice then to observe what Doctor Cantwell has related. In a house in Scotland were four children; one of them caught the fmall-pox; their father let two of the others be inoculated, but ordered the fourth to drink tar-water; all these four lay in the same room; those three who had the fmall-pox were fuccessfully cured, but the fourth who drank of the tar-water did not get infected; the father fuffered it to be inoculated and to drink the tar-water again; but the contagion did not take. Two months after the inoculation was tried again, and no tar-water given it to drink; the child then at last got the small-pox, but of so gentle a kind that we could scarce look upon it to be diseased.

Some years ago, and in the parish of Longthora, which is fituated about 15 English miles from Upfal, a small-pox raged, of so malignant a kind, that almost every child who was attacked with the disease died: as soon as their parents, on my intreaties, let their children drink some tar-water, both before and during the disease, the contagion turned so favourable, that fcarce a fingle one died.

The preparation of tar-water may be made as follows: take fix quarts of water, and three pints of good tar, flir them together for three or four minutes with a fpoon or a fpatula; when the veffel has afterwards ftood for 48 hours, and the tar has had time to fettle at the bottom, decant the clear water, and put it by in bottles; this is transparent, and as white as Spanish wine; its tafte is fomething fourish, and 'grows ftill 112

ftill more fo if we evaporate a little of the water, and then it changes the colour of fyrup of violets into red, and ferments with alcali; it confifts of a fine oil, which by means of a finall portion of its acidity is kept diffolved in the water, and confequently makes a fine foap; of a diffolvent, and at the fame time antiputrefcent quality:

In the year 1744, when a fevere fmall-pox raged at Upfal, I began to give children prefervative pills; and had the pleafure to find, that all those who took them, either did not get the fmall-pox, or had a very favourable kind. They have afterwards been used over the whole kingdom with the same success; and I never as yet heard that they failed, when the parents of the children had seen that they were really taken. Take the composition as follows:

R. Calomel rit. ppt. gr. xii, Camphora, gr. viii. Extracti Aloës, gr. xii. Gummi Guajaci, gr. xvi. M. f. f. a. Pill. pond. gr. 2. Foliis argenti obducende Dr. Sr. Prefervative pills:

The dofe may eafily be afcertained for each perfon, that being the proper quantity which procures three or four stools. For instance, a child two years of age may take three pills; one three years old may take four; one five years old may take fix; but a child being more than seven or eight years of age, must not take more than feven : if this dofe fhould not be fufficient to procure ftools, then I add to each dole of the pills one or two grains of the rofin of jalap, previoufly well rubbed with almonds. These pills are to be taken twice a week; for instance; every Sunday and Wednefday in the evening, and then they will operate on the Monday and Thursday in the forenoon. During the use of this medicine one ought not to eat falt food, and meat only at dinner; one may walk out in the open air as much as one chufes; except on those two days the pills are operating. When we know that the small-pox is in the neighbourhood, or in one's own houle, or we cannot avoid feeing those who visit the houses where any one is affected with the fmall-pox; then

then we ought immediately to give of the above-mentioned pills to the child, letting it continue taking them till either the contagion has ceased, or till we are otherwife fure that it cannot reach the child : if we leave off the taking of the pills before that time, then we cannot attribute it to their fault, in cafe the smallpox fhould prove of a bad kind; we ought never to take a great quantity at once from the shops, for the camphire is eafily volatilifed, which however is most conducive in preventing the contagion; therefore the infection will not succeed, if the variolous matter be mixed with camphire and pomatum : but one may inoculate the fmall-pox with this unguent, by its being well rubbed on some part of the skin, provided the camphire is left out. That Calomel diffolves the blood, but efpecially the humours, is very well known; that it prevents the infection of the fmall-pox, may eafily be inferred from the cafes I have given in the transactions of the Royal Academy of Sciences at Stockholm, for the year 1751, page 32; and confequently these pills must, in respect to the small-pox, be of a much greater effect than only fimply to purge; that they have been of fervice, is fufficiently proved by narratives, from the provinces, published in the news-papers. I am for the most part certain, that every child who is otherwise healthy, flrong and well fed (for a weak child ought rather to be prepared with the Jesuits bark), will have a favourable kind of small-pox; 1. If it continues the use of these pills for four weeks; 2. If during that time it does not live on much nourifhing food, and eats but little meat, 3. then vifits any body affected with the fmall-pox, and as foon as it is found thereby infected, 4. purges by the pills again, and 5. fuffers itfelf to be fcratched, or fcarified on feveral parts of the fkin with a pin or a lancet, as for inftance on the arms and This latter will be of very great fervice and legs. importance, as we know, if any body happens to fcratch himself by a pin, or any other accident at the time of eruption, many pustules will break out on both fides of the scratch, in the same manner as they break out round the incifion made for the inoculation, 1 moreover knew a child that got a fevere whipping on its posteriors by an impatient mother, the day before the T eruption;

114

eruption; this was attended with fo good an effect, that the child got only one postule in the face, but a had a great many about the marks of the rod; confequently the above-mentioned foratches made in the fkin, are the best remedy to preferve the face.

In the northern provinces of Sweden, it is cuftomary to hang a little mufk on children, as a prefervative against the fmall-pox when it is spread in the neighbourhood. I have not as yet had sufficient experience of this; I should think it would succeed, provided it were true, that the variolous contagion depended on infects: but another method of inoculating used by the Chinese, (for they have several methods) seems to be something against this. They take one grain of musk, putting it betwixt two large, or four smaller scales or crusts of the pocks; this is enveloped in a little cotton, and put into the nose \*.

Others again are accustomed to carry quickfilver on their body, in order to prevent the infection of this difeafe. Belloste relates, that a noble lady had carried it on herfelf above 50 years, and was then passed the 80th, without having had the fmall-pox : Bellofte himfelf used it in the fame manner continually, and with the fame intention, and had not then had the finall-pox in his 70th year; he was of opinion, that the quickfilver forms a vapour about the body which the infects fly from; for he looked upon them as the caufe of the small-pox, plague, and other eruptions: it is very probable that quickfilver fends fuch an exhalation from it, for if we lay a little of it in the middle of a large diffi, and afterwards a lumbricus on it, we may perceive how the worm feems to be in pain, and retires to the edges of the bason with all its speed, and to the utmost of its power. Allowing such remedies not to be of great fervice, they will however

\* In the cafes which the society of furgeons have printed in Stockholm, for the year 1769, fat of feals is praised. It is faid, that the pocks will be but few and favourable, if any one who is infected takes twice a day a few drops of an oil expressed from it, continuing it till the eruption is performed.

5

do .

do no harm \*; they quiet the minds of many who otherwife would be in daily fear, and in that respect, at least, they are useful.

A lady from Finland, fome years ago came over to. Stockholm, and disclosed to the court a remedy which she had tried, in order to make the number of puftules in the imall-pox but inconfiderable; it was communicated to me, and confifted in only this, that the patient fhould wear scarlet cloth on his body instead of linen, and have his face covered with the fame. I applauded her good intentions, but looked upon the remedy as infufficient: I have fince found that Doctor Miag, at Bafil, let a child, on which he had inoculated the finall-pox, from the beginning of the fever lay with flockings on made of scarlet, without soles. He expected that they would drive the small-pox down to the feet, by means of the gentle friction or titillation they would caufe, as well as by the retention of the perspirable matter; and hoped thereby to preferve the face. When the time was elapfed in which the fmall-pox ought to have appeared, the stockings were taken off, expecting to find a great number of pustules in the legs; but to his great furprife he found only a couple of them there; as the body was well prepared, and the pores well opened by baths and washings, it appeared to him probable, that the greater part of variolous matter had thereby perfpired; he proposes besides to strow some irritating powder in fuch flockings, for instance, as of mustard feeds. See the AETa of Zurich, vol. iii. p. 103. He tried it afterwards, but was obliged the next morning to take off these flockings so bestrowed, as the child could not suffer the heat and irritation they caused. See l. c. p. 121.

\* The rich are generally cheated by fuch remedies; as it happened with Arnold's bags against apoplexy. Their use at last ceased, when it was found that some of those who had worn them died notwithstanding, of the apoplexy. It is however happy when such remedies do not occasion any mischief, as it happened to those, who in hopes of avoiding the plague, bought and wore on their breast an amulet of arfenic. See Diemerbroek de peste, l. iv. p. 319.

12

Doctor

115

Doctor Casim. Medicus has for a long time confidered of the methods of eradicating the fmall-pox, and thinks that he has found the means for it, which he discovers in the second volume of his Samlung von Beobachtungen, p. 182. He once began to give his patients only the tincture of bark in some distilled water, when a fevere kind of fmall-pox raged, but not till after the eruption; this he found to make the disease savorable. He gave likewise the tincture of bark to a child half a year old, from the first beginning of the difease, and found that it only had two pocks. See I. c. p. 726, to p. 732. This encouraged him to go still farther. As he knew that the first fever of the finall-pox was an inflammatory one, he thought like-Boerhaave, that if this fever could be subdued, no eruption would enfue; therefore he advises to use from the very beginning, all that is proper in inflammatory fevers, as bleedings, emolient clyfters, cooling emulfions, and a copious drink of barley water : but the peculiarity of his discovery is, that at the fame time he gives the bark in powder, which perhaps no one before him has thought or ventured on. He is however careful to cleanfe the ftomach beforehand with an emetic, in cafe it fhould be wanted, and in that he is very much in the right, as the bark will be inefficacious if the flomach is loaded with flime, bile, or crudities; fhould any thing of that kind be in the bowels, then he prescribes purges of manna, tamarinds, and a little jalap; or he gives magnefia and cremor tartari together with an emulfion. If the first fever is not very high, he uses only to mix the bark with a little cremor tartari; if, contrary to our expectation, the fmallpox fhould break out and not immediately difappear, then he advises to apply a vesicatory of cantharides, which is to drive the eruption to fome place where it cannot deform the patient, or do any harm, and to prepare an exit for the variolous matter by the fame means.

All this founds extremely well; time will fhew whether experience will confirm it or not. As far as I can find, the author feems not to have yet tried it in the year 1765; but only makes this conclusion in confequence

### AND THEIR REMEDIES.

confequence of the theory, and the fuccefs of the method in other inflammatory fevers, (see l. c. p. 432 -464.) and by the fimilarity with the measles, miliary and other petechial fevers, &c. He also advises to try this on children in inoculating them, in order to find whether the bark would then prevent the eruption.

The late professor Monro relates, that a lady fuffered her children to use a bath every day during the course of a fevere small-pox; the bath being prepared of water and juniper-berries, and their room befides fmoaked with the juniper-tree; this had fo good an effect that among eight or nine children, not one was infected : I should not have mentioned this, had not fo great a man as Dr. Monro recommended the trial of it.

However, the fureft method to prevent the dangerous effect of the fmall-pox, is to inoculate \* it on children, while they are ftill young, and in the manner as is now cuftomary in England +. It is both very difagreable

\* See more of this in the perfect and well written narrative by Professor Dav. V. Schulzenheim, on the inoculation of the fmall-pox; and in the extract of Mr. Chaife's Effai apologetique, under the title of Answer to the Objections, &c. published in Sweden by Mr. Rosen, first chaplain to the king.

+ The famous lady Mary. Wortley Montague is the first who introduced the inoculation of small-pox into Europe. She had her fon inoculated at Constantinople, at the age of fix years; and her daughter inoculated in 1722, after their return to England. However, for the fatisfaction of the court, the experiment was first made on fix convicts, who were fuccefsfully inoculated, and thereby escaped their sentence of death. The great king Charles the XIIth of Sweden, during his stay at Bender, ordered a circumstantial narrative to be written concerning the inoculation of the fmall-pox, and with what great fuccefs it was practifed among the Turks; this was fent to Stockholm, but I have not as yet been able to find out whether any one at that time made tryal of it in Sweden.

It is both strange and unaccountable to find how many means have been taken in England, by those who were against the inoculation, in order to deter the nation from it.

I 3

disagreable and inconvenient to lie under a necessity, either to take the *æthiops* or the prefervative pills, or to

Among others, a wretched fellow named Jones, related that he had fuccessfully inoculated his daughter, but she three weeks after that got the fmall-pox again by the natural infection; on inquiry, he was obliged to confess in letters to Doctor Jurin, that he did not know what inoculation was, and that he had never inoculated any human being during his life. Kirkpatrick has introduced the whole letter in his new edition of the Analysis of, Sc. p. 147. The inoculation of the fmall-pox has met with no declared enemy in Sweden, but most likely has some secret opposer; as the writings of M. de Haen have been placed in houses of the utmost consequence, without being able to discover from whence. In the year 1761, feveral houfes were mentioned, in which it was faid that inoculated children had got a fevere small-pox again. I went on purpose to visit both the parents and children, and found, on enquiry, that all was an impudent fiction; this, and all the inventions employed in England, have perfuaded me that the cafes which are related from other countries against the inoculation, may be equally false and uncertain. Those who chuse to know the origin and fate of the inoculation in this kingdom, will find it in a well composed gradual differtation, by professor J. A. Murray in Gottingen 1767, intitled, Historia institionis variolarum in Succia. The Dr. and Assessor Hast has done the greatest service to inoculation in this kingdom; he inoculated in one year 229, the greatest part of the children of the common people in Oesterbothnia. We cannot fufficiently extol the great care of his majefty, who in a confpicuous manner has encouraged both the Doctor and the common people to this purpose. See the news-paper from the provinces for the year 1763, No. 86.

The royal college of phyficians have likewife continually encouraged the phyficians of the provinces to inoculation, and chiefly fent the Doctors Aman, Nordblad, and Sablberg to Norrland, and Ekman to Oftrogotbland, where they have inoculated a great number of the common people's children. Affetfor and Doctor Wablin has also inoculated as many fubjects as were to be met with in Jonköping, as also feveral children fent to him every day from the country; the inoculated were fuffered to walk about, nevertheles the infection was not spread : a fingle child on which the inoculation

did

to drink tar-water for a long time at each contagion of the fmall-pox; but it is dangerous to live exposed to this fevere difeafe when the body is not well prepared; and there is still more danger in not being infected before we are advanced in years. We may be fur-prised by the small-pox on our travels, at an inn, or at places where we must be destitute of both phyficians, proper medicines, and nurfing ; we may happen to catch the infection during the heat of the summer, when we have lately been exhaufted by fome other fevere difeafe, or by night-watching, or by labour; or at the time some more severe epidemical disease is raging, fuch as the miliary fever, pleurify, peripneumony, and petechial fevers; or when we have been overloaded with fpirituous liquors or improper food ; or from the body being full of bad humors. Ladies especially ought to infift on being inoculated, as their beauty is so often lost or endangered in the small-pox by the natural infection; their own life and that of their fætus being greatly exposed thereby during their pregnancy. The many instances of those who by this disease have lost. their fight, hearing, and fpeech, are ftrong motives enough for us gratefully to accept of a remedy which prevents all these missortunes. The more sensible perfons, who know that the lofs and want of people is of great consequence to a kingdom, and that the tenth part of Swedish children are carried off by the smallpox, ought by their example to actuate others to inoculation. What a great loss is it to a country like Sweden, to lose yearly 9000 persons by the fmall-pox and measles \*! We ought likewise to be encouraged

did not take, was infected by being in the fame room with its fifters who had the fmall-pox from inoculation. Want of room and opportunity hinders me from enumerating any more: each in his province has fhewn how useful they are to their country.

\* One of the commissioners for counting the people has communicated to me the following List of the number of those who within 16 years have died of the small-pox and measles.

I 4

Years.

encouraged to this by the example of other civilized nations, who have already received this remedy, and found it to be both innocent and ufeful, and the beft reparation for the want and lofs of people in a kingdom; and befides, I am daring enough to advance, that we ought to allow ourfelves to be perfuaded to inoculation by phyficians, who ought, and do in fact underftand it, and are proper judges in those matters: every thing is in favour of inoculation, as theory, experience, religion and morality: in the fmall-pox of the natural contagion, one perfon out of feven dies that are infected \*. In the hospital of *London*, where those are taken

During the fame time in Sweden were born 1,391,233 children, of whom 709,090 were boys, and 682,143 girls; confequently every 10th boy died in the fmall-pox or meafles, and nearly every 9th girl, or more accurately 100 among 936: the two difeafes are put together in the lift, tho' they ought to be feparated. But as the meafles are much lefs *lethiferous* than the fmall-pox, the number of dead above mentioned are for the greateft part owing to the laft.

72902

\* Mr. De la Condamine (Lettre a Mr. Maty, 1763) shews that in France 30,000 perfons are lost every year in the fmall-pox, and that 25,000 of these might easily be faved by the inoculation. We are in a great measure obliged to him for the lives which are faved in Sweden by means of the

### AND THEIR REMEDIES.

taken care of who get the ordinary small-pox, two are lost out of nine. Some years ago 270 died of this disease out of 300 children of the soldiers of the royal guards : among those who are inoculated only one of 250, 425, or 500; nay if the preparation has been good, and nurfing alfo, perhaps not one would be loft out of feveral thousands; the ordinary small-pox will mostly infect the face; in the inoculated the greater number of pustules breaks out on the arms, and the variolous matter is in part discharged through the wound of incifion \* : the eruption feems however not to be diminished by that, as the suppuration of this incision, is not very great in the beginning. It is faid that the ordinary small-pox may return, tho' I never have feen it, nor has any one of the most accurate observers and phyficians, as Boerhaave, Mead, Chirac, Molin, and the phyficians in Scotland and Sweden ; but of the many thousands inoculated we have not had a fingle such instance + that is well authenticated. I cannot look upon

the inoculation; for it was owing to his correspondence with the Count and Senator *Scheffer*, that the inoculation was supported and encouraged by the Senate.

\* What Mr. Gandeger Foigny fays, in his Traité de l'Inoculation, p. 278, feems not to be in confequence of experiments; it would be worth while to try it.

+ That the inoculation did not properly fucceed on the five fifters, who were inoculated by the late professor Roe-derer, is demonstrated by professor Wrisberg, in his excellent treatife called, De Institione Variolarum momenta nonulla, Mr. Foigny relates, l. c. that Doctor Richard de 1765. Hautestercy inoculated a young person every fortnight for a whole year; the first of these inoculations took, but none of the others did; this young man was not in the leaft injured in his health by fo many inoculations. Dr. Maty let himfelf be inoculated, but without any effect, for he had already had the fmall-pox before by the natural infection. Mr. Gatty fays, that if an inoculated perfon only get a fingle pustule, that the pus in that ought to cause small-pox for the second time, and the *pus* in those for the third time, and so further, for he would look upon it to be as many inoculations; but fuch a thing has never yet happened. When the question is, whether an inoculated perfon who has not got a diffinct eruption, can make himfelf fure of not having it again, or not? Mr. Foigny aniwers,

122

upon the contagion of the fmall-pox to have taken by inoculation; I. If the edges of the incision have not fuppurated any thing; and 2. no fever has followed on the 7th, 8th or 9th day; and 3. after that no eruption either more or lefs has broke out, of which a part has ripened, suppurated, got crufts, and at last is fallen off; or 4. in cafe no eruption has happened, and the wound of the incifion has notwithstanding discharged a copious matter for some time. That this is a variolous matter, is fufficiently proved by Mr. Wall and Mr. Gibbes having inoculated others with it; fee Kirkpatrick, c. i. p. 164 and 413. A noble lady was inoculated four years ago, and got only eleven puftules; immediately after that fhe flept in the fame bed with her coufin, who then had the fmall-pox, and without being infected. Profeffor Schulzenheim inoculated 37 children in the hospital which is kept at the expence of Free-masons in Stockholm; three years after that, when 17 other children were naturally infected by a malignant small-pox, of which nine died, the former did not receive the least injury, tho' they lived in the fame fame room with those thus feverely infected.

The inoculation will not take in any one that has not a difposition to the small-pox : nevertheles he may find himself thereby secured and freed from that daily fear of being infected, which he otherwise would have had reason to apprehend \*. We do not tempt the Al-

fwers, that we ought to take notice of the incifion wound, whether it be round or oblong, large and fhining: from that cafe he fays, that fuch a perfon has had the fmall-pox. In a negro, inoculated by professor *Schulzenheim*, I faw myself that the fcar was in the beginning whitish, but within a short time turned black again.

\* My old true and worthy friend V. Haller, prepared his daughter for inoculation for four weeks together, in the year 1757; fhe was not then 15 years old, but had her menfes. She lived during the time only upon vegetables, ufed warm baths for the feet, and took purges; then the inoculation was performed, but ineffectually, for it would not take, tho' repeated three times. She was afterwards married and had feven children, the greater part of whom fhe nurfed herfelf during their fmall-pox, without being infected. See his Opujc. Min. iii. p. 356.

mighty

mighty by the inoculation of the fmall-pox; nor do we thereby oppose his omnipotence; we are not fo daring as to implore him for a miracle, but use this as we might another 'natural prefervative and remedy, which he has gracioufly defined for mankind, whereby they may fubdue an unavoidable and frequently lethiferous difeafe. Why should we think it fin, to receive this bleffed remedy gratefully, which providence has been pleased to suffer to be discovered, and which has already faved fo many thousands of lives? Nay how can it be confistent with an honeft and good confcience, to fuffer the natural infection to ravage among mankind, and defpife or neglect a remedy which we know can preserve us from the danger? See his excellency Count Teffin's letters to the Hereditary Prince of Sweden, the second Volume.

I hope no more arguments are wanted to perfuade my countrymen to receive the inoculation univerfally, efpecially as it has already with fuch great fuccefs been performed in *Abo* and in *Upfal*, and 1757 in the month of *March* at *Stockholm*, in a noble family \* whofe example feveral will certainly follow  $\dagger$ . Now only remains

\* M. de Geer, one of the lords of his Majesty's bed-chamber, together with his lady Baroness Ribbing, refolved to inoculate their four children; which so much rejoiced the great counsellor. Count Tessin, that he in memory of this, ordered a medal to be struck, on the one fide of which stood the name of the Baroness, with this inscription, Ob infantes civium felicia usu servatos, and on the other side a structure in the inscription, Sublato sure nocendi.

+ This really happened afterwards, as may be feen in the narrative of the phyficians of the provinces, fent into the college of phyficians, printed in Stockholm, 1761. What is most happy to the whole nation, the inoculation was in a happy hour, in the year 1769, likewise received into the royal family, and fuccessfully performed on five of them: four were first inoculated within the fame hour, and the fifth fome weeks afterwards; all of them fell fick on the fifth day; four were inoculated by a fmall veficatory of cantharides, and the fifth according to his own choice by in-The varielous matter for inoculation was taken the cinon. day before; the wounds were alike in all, the crufts on them acquiring a dark pewtery colour on the feventh day, which was the day before the eruption. All were before prepared for

mains for us to confider how the inoculation itfelf is to be performed.

The fmall-pox' may be inoculated on young and old, full grown perfons and tender infants: I rather would not chuse to inoculate on the latter, before the meconium is carried off, and a time fixed, in which we have nothing to fear from the teething; their nerves are then too fenfible, and thus are liable to get convulfions at that time, which always make the profpect dreadful. Neverthelefs, I know that it has fucceeded with profeffor Schulzenheim, who has feveral times been obliged to do it : Dr. Maty recommends it with very good arguments in the Medical Essays, Vol. III. p. 287, and Doctor Locher at Vienna, in the year 1768 inoculated 34 new-born children, of whom the oldest was only feven days old; it is rather to be admired that only one died; for both the room and nurfing were bad; the mother of that child who died, had contracted a diarrhœa by walking on a ftone floor barefooted, and keeping her diforder fecret. See Maxim. Locher's observationes, practicæ circa inoculat. variol. in Neonatis instit. Vindobonæ, 1768. Dr. Dimsdale excludes only from the inoculation, fuch as are affected with inflammatory or exanthematic fevers, or have evident figns of acrid and corroding humours, who pine away, or frequently are troubled with agues. He rather excludes women who are big with child ; but he pretends that those who have laboured under any chronical distemper, disposition to the king's evil, fourvy and gout; or are corpulent and inactive, or have lived immoderately, have been inoculated with the fame fuccefs as the moft healthy and moderate. See his l. c. 1 would rather cure pimples of the face before I inoculate, which may eafily be done by a good diet and the above-mentioned pills of calomel, sulphur auratum antimonii, &c. and by purges.

Girls who are in the 14th or 15th year fhould not be inoculated, unless they are otherwise very well in

for a fortnight together, by a proper diet, and pills of calomel, *fulphur auratum antimonii tertiæ precipitationis*, camphire and *gumm. guaiaci*; thefe pills were taken twice a week, and the following day a gentle purge, accommodated to the taffe of each.

respect

# , AND THEIR REMEDIES.

respect to, and just after the three first days which are ufually troublesome to their fex. We ought carefully to avoid inoculating any one who is perhaps infected already, as then the pustules will break out too foon, and if they be malignant, it will be afcribed to the inoculation; therefore whoever is to be inoculated, should first keep within doors for about a fortnight, fo as to prevent the contagion reaching him; this is eafily attained by those who have more rooms than one, fo that the child may stay in the inner apartment, where none fhould be admitted except those who are to attend the child. We find the importance of this from what Dr. Archer relates to Doctor Kirkpatrick, that among 33 children he intended to inoculate, 11 were infected with a natural fmall-pox during the time of preparation, by which three of them loft their lives; see his Analysis, p. 412. One ought not to adinit any one who comes from a place where any other contagion is fpread, to fee the patient who is inoculated : it once happened that the hooping cough was conveyed to one of my patients, who had the small-pox; the pustules were drying when the child got the other disease, and would have suffered much if the small-pox had not been so favourable, that scarce any thing of its ftrength was loft; the child was likewife cured of this difeafe, but with more difficulty than the former. I was fo much the more convinced that this had been a true hooping-cough, as befides the difease being attended with the ordinary fymptoms, the child was not infected the following year, tho' it was for three weeks together in company with two other children who had a violent hooping-cough.

Nobody fhould be inoculated who is not (if it be wanted) well prepared; which is to be done by the above-mentioned prefervative pills \*; in the mean time taking

\* Or by one or two grains of calomel taken together with a grain of camphire in a wafer towards night, and the next morning a moderate dofe of *electuarium lenitivum*; confequently we find, according to my own repeated experience and that of many others, the precaution of M. de Harn

taking care to avoid excels in food and drink, in labour, exercise and night-watching, leaving ftrong nourishing food, or that which is falt, imoaked, four, hard, seasoned or rich, especially at supper : those who are weak may be allowed to feed better than those in perfect ftrength; for the body ought to be put in fuch a condition, that the variolous fever does no harm without being fuffocated, for in that cafe the puffules cannot break out, rife, ripen, and dry: for all our intention by the preparation ought to confift in effecting, 1. That the body does not suffer by any other disease than the fmall-pox. 2. That the blood be neither too rich nor too poor, as the fever in the former cafe may be too violent, and in the latter too flight; in which latter cafe, the variolous matter might, according to the vulgar expression, lay itself on the nerves. 3. To soften and relax the folid parts in cafe they feem too hard, dry, and rigid, and e contra to ffrengthen them if they are too relaxed. 4. To correct a bilious constitution, for that is generally attended with a fevere fmall-pox : of fuch a nature was that of the universally beloved Count Gifor; who was inoculated in the 24th year, but by the means of a good preparation, went through this fickness with ease: therefore if a person be plethoric, he should be bled the fame day the inoculation is performed: those who are of a dry and lean constitution, ought to bathe in warm water feveral times; if they have weak lungs, they ought befides to drink whey, (petit lait) or fresh and strained butter milk; but if they are affected with any other difeafe, as loofenefs, worms, fcab, boils, miliary fever, or any thing fimilar, these difeases ought to be cured \*. Children who generally are

Haen to be quite unneceffary. Affeffor and provincial phyfician Dr. Haft, has inoculated 55 children of the common and poorer people, with the greatest fuccess, and without any preparation, as they most likely did not want any. See the News-paper from the Provinces, No. 62, of the year 1770.

\* Such diforders ought certainly to be cured beforehand; but fickly perfons then are not at all to be inoculated ? If

the

### AND THEIR REMEDIES.

127

are great eaters, ought to be prevented from gorging too much, neither ought they to be fuffered to heat themfelves

the inoculation is a remedy which makes the fmall-pox lefs dangerous and more favourable, and the fickly be as much exposed to the contagion as others, it plainly follows, that the benefit of being inoculated ought not to be denied them : for if they are with difficulty cured of the fmallpox when inoculated, they certainly will lofe their lives by it, if gotten by the common contagion, as it is most probable that they will have a fevere kind. In the interim, we should rather chuse healthy subjects to inoculate on till this operation be generally received, and looked upon to be as innocent a remedy as bleeding, or the use of mi-neral water. When from the public it has gained such confidence, we then may go on still further, and use this happy remedy for other diseases, which are otherwise commonly incurable, as mental diforders, the hyp, convulfions, epilepsy, paralysis, gutta-serena, stubborn agues, &c, We have now hopes of performing great things by the inoculation, on reading what Dr. Lobb relates in his book on the fmall-pox, Tom. II. hift. xlix, of a youth 12 years of age whom he inoculated; and from what is mentioned in the Literary Gottingen Gazette, 1757, p. 1300; as also from the story of Mr. Williamson, whose fickly constitution was fo far mended by the inoculation, that his friends did not know him. (see Kirkpatrick, c. i. p. 276). Professor Schulzenheim inoculated the fmall-pox on a child which had a weak fight; but as foon as the fmall-pox was over, its eyes were much better. A noble young lady who was inoculated on the leg by professor Haartman, thereby got rid of a running of the eyes of many years standing. Professor Schulzenheim and Bergius, have experienced the fame by inoculating on the arm. I will here likewife mention a remarkable cure performed by professor Muzel in Berlin, 1754: he received into the hospital a man about 28 years old, who through grief for the impious conduct of his fisters, had ruined himself so far that he had only the resemblance of a man; he gave not the least fign of sense or. feeling, was lean and pale, and had a weak and flow pulfe : he was retained in the hospital for two years, and all possible means were thought on and tried to relieve him; as nothing fucceeded, he was inoculated with a fcab, which the following day caused a violent fever, with fuch a falutary, effect,

themselves by too much playing; they ought especially to be prevented from fuch plays by which they may hurt themselves, (see the Asta of Zurich, Vol. III. p. 68) : girls ought at that time to pull off their flays; those of a bilious constitution, ought to drink freely, and to take one or the other emetic, abstaining from all milk and fat food : they fhould mix in their foups and flews of herbs, a little juice of lemons or good vinegar : those who cannot take the pills may be prepared with the tar-water during three or four weeks beforehand, and take a gentle purge every fourth day of the electuarium lenitivum, or something fimilar, according to the constitution and age of the perfon : those who cannot bear the tar-water, may content themfelves by keeping a good diet, and fometimes purging, However, I have the greatest confidence in quickfilver, especially as I cannot find but that it otherwise diminishes the disposition in the body of receiving and nourishing the variolous matter, or elfe how would the method of Baron Dimfdale succeed so well as it does? I conceived that opinion in 1744, when Mr. V. G. was affected with a confluent fmall-pox, and I wifned to fecure his two brothers from fo malignant a kind, which likewife fucceeded, by the ufe of the above-mentioned pills: one of these two continuing the use of. them likewise after the fever had began, without my knowledge, he got a slight eruption on the 3d day, which on the 4th disappeared, together with the fever : he continued however very well, and got the variolous fever a fortnight afterwards, and only five puftules. Dr. Watfon in London, tried to find out the difference between inoculating with and without preparation, in the following method ; he inoculated eight children after the new method, one half of which were boys and the other half girls, from fix to twelve years of age, they being prepared by a couple of purges of 10 grains of jalap and four grains of calomel; the puffules counted together made, at a medium, 14 for

effect, that the patient quite regained his understanding on the 9th day, and was able to leave the hospital after three weeks, perfectly restored to his health.

each

each boy, and five for each of the girls: four other boys and as many girls were likewife inoculated; after being prepared with a laxative of *infufum fennæ*, and the *fyrupus rofarum*, the number of pultules counted at a medium, were about eight for each child: but of 11 who were inoculated without being prepared by any purge, the medium taken of the number of puftules amounted to 32 for each; all thefe were nurfed alike: now if the danger of the fmall-pox depends on the number of puftules, every one may from this eafily judge of the utility of purges during the preparation alio in younger children. See Archiater Bæck's preface to Dr. Dimfdale's book on the inoculation of the fmall-pox, p. xv \*.

As a proper drink during the preparation, we may use water mixed with milk, good small beer, or a ptifan of radix chinæ. Mr. Tiffot recommends very much whey or petit lait, and that with good reason : as a proper food, we may prescribe dishes prepared of milk, gruels, groats, bread and foups; frying fifh, hathes of fifh, or fifh flewed with rafped bread, or with the leaves or the roots of parfley, however this ought to be done with but very little butter; fpinage ftewed with foup for dinner, and without foup for fupper; fpinage or other greens stewed with fresh cream is good, but ought to be lefs frequently ufed : a child may eat puddings of bread, or fpinage, fome forts of cakes and wafers, but no pancakes, or fuch as are fat. Those who appear tender and are weak, may be allowed to eat veal and chicken broaths, and hash meat : those who are not troubled with a loofenefs, ought frequently to eat diffes of herbs, and flews of apples and plumbs, for they ought to have stools every day : the poorer people who cannot afford fuch a variety, may content themselves with milk barley-foups, groats, ale-foups, milk-whey made of small beer and the like: we may eat the dinner in a due quantity, but supper ought to be reduced, as otherwife the food will not be digested, and the fleep will be uneafy.

There is however no poffibility to give any general rule for the preparation, as different conflitutions of

\* The Swedish Translation.

K

bodies,

bodies, will require different preparations. A tender and weak child, who is often plagued with acidity in the flomach, vomitings or too great a loofenefs, or who has fome figns of the rickets, wants a longer preparation, than one who has a good appetite and is of a healthy and jolly appearance; this latter needs only to be reduced to a lefs quantity of food, and to drink whey. Children are well prepared when they are hungry at the cuftomary times, fleepy and awake at the usual hours; when they have a due number of stools, the lower part of the belly foft, and the breath fweet; when they are in good spirits, and feel themselves active and light. If at the fame time it happens, that the air is not too hot, too cold, or too moift; if no other contagion is raging which likewife attacks children, and the perfon to be inoculated does not fear it; then we have the greatest reason to expect good success.

The matter for inoculation may be taken from the wound after the incifion, either by the point of a lancet The confirmations of Sutton; or by a cotton thread. Watson, Dimsdale and others, shew that we need not wait till it becomes yellow or ripe; they pretend likewife, that the unripe matter will cause a less number of puftules when their new method is used, and that very little of it is required to propagate it : however Dr. Dimsdale seldom depends upon a fingle incision, but makes another in order to make himfelf the more fure that the contagion shall take : he likewise collects the matter for inoculation during the eruptive fever, in expectation that it is then more effective. When he collects this matter from an inoculated perfon, it is taken from the wound of incifion, being very well convinced that the matter taken from thence is powerful enough to infect, in cafe the contagion has taken in that wound : the fresher the matter is, so much the better it will be : there is fometimes fcarce any variolous matter to be got in the smaller towns and in the country; therefore it is neceffary to preferve fome dry threads for inoculation in a phial to use occasionally, by which we can foon get a fresh contagion; we cannot exactly fix how long a time it will preferve its power to infect; but Mr. Fiffot has inoculated with fuch a thread 26 months old, and Kirkpatrick with one, which was preferved five years

IZI

years and 11 months: we may likewife keep fome crufts of the fmall-pox for the fame purpose, as is practifed by Affeffor Haft.

The best time for inoculation is when the perfon to be inoculated is under fuch circumstances as are above enumerated as favourable, either during the fpring, fummer, harvest, or winter; because it is now performed in all feafons, and with equal fuccefs : the inoculation is performed in Constantinople during the winter only, as either the plague or the peftilential diforders commonly rage during the other feations of the year. We ought however to defer the inoculation if any other epidemical diftemper rages; this is likewife agreeable to the opinion of Baron Dimsdale. The late profeffor Monro relates, that a certain phyfician, during the time he visited many patients in the miliary fever, inoculated the small-pox on his own fon : he was affected with the miliary fever upon the eighth day; but this was foon cured; after that the fmall-pox broke out, and was likewife favourable : feveral others were inoculated by the variolus pus taken from this patient, and all of them were affected with the miliary fever together with the fmall-pox : the event was fuccefsful, neverthelefs I think it imprudent. Vide Journal des Sçavans, 1766, for Jan. p: 227.

The patient ought to take a gentle purge the day after the inoculation; he may likewife then begin to bathe his feet every night in warm water. I make the incifion on the arm just at the place where iffues are commonly made; we may inoculate on both arms, in order to be certain of the infection fucceeding: I rather choose the arm than the leg for this purpose, in order that the patient may be able to walk during the disease. We may make a fcratch of the length of about half an inch, between the upper and inner skin, obliquely with a lancet, fo that fcarce any blood comes out; in this wound we put the thread for inoculation, not covering it with any plaister (unless perhaps the first day), but only with a bandage to prevent the thread from falling out; a little cotton fhould be put between the wound and the bandage, as they otherwife might stick together; digestive unguents are unnecessary. Children K 2

132

Children are generally frightened at the incifion, efpecially if it is to be done in more than one place; therefore I think it much more proper to use a velicatory inftead of it, which is oblong and but very fmall\*; we apply it in the evening, and take it off again the following morning, together with the thin elevated ikin, drying the place with foft linen; after that the thread for inoculation is to be put in it, which we fecure by means of a little cotton and a bandage : if after one or two days there is no rednefs found on the edges, we may put another thread in, and if it be wanted likewife the third and following days: I have as yet never found this to be attended with the leaft inconvenience as M. de Foigny pretends. We may eafily follow the advice of proteflor Schulzenheim, and apply three different threads at once, which certainly will make the infection fucceed; four perfons of our royal family here, were in this manner inoculated. Baron Dimfdale admits the perfon going to be inoculated, into the fame room where a patient lies affected with the fmallpox, and fetches fome variolous matter with the point of his lancet, either from the wound of inoculation or (in a natural fmall-pox) from a puftule, fo that both fides of the lancet are wet; with this he makes a little opening, on the arm, and no deeper than that it pierces through the exterior fkin, and only touches the interior; and with respect to its length, as short as poffible, and no more than the eighth part of an inch; he extends this fmall aperture by the thumb and his fore-finger, striking gently over the wound with the flat fide of the lancet : the wound is in this manner moistened by the infection (see c. i. p. 16). I think it would be fafer not to admit the perfon going to be inoculated into the fame room, tho' he may come into 3 the fame house where any one is affected with the Imall-pox. Professior Schulzenheim and Dr. Ahman,

\* Affeffor *Haft* looks upon this likewife as the beft and fureft way. He puts in it a couple of fcales of the fmallpox, which he endeavours to cover with the thin elevated fkin *(epidermis)*. See the reports of the phyficians to the provinces, to the *Cellegium Medicum*, 1769, p. 543.

who

# AND THEIR REMEDIES.

who fometimes have inoculated in the manner of Baron Dimsdale, always made the incision in the next room to that of the patient, which was attended with. fuccess: what is to be further observed in respect to this new method, may be seen in Dr. Dimsdale's book, and in the preface which Archiater Back has written to it in the Swedish translation. Last spring I inoculated three children in the country, two of them in the manner above described, and the third after the method of Dr. Dimfdale, only with this difference that I used a vesicatory and thread instead of a lancet: the inoculation did not fucceed in one of them, notwithstanding I applied new threads; its mother recollected afterwards that it had had the fmall-pox before; the other got a favourable small-pox, but was so peevish that I could scarce prevail on it to fit up at all, much less to walk out in the open air; the third had the difease in a very easy and gentle degree, was chearful, and walked out in the cold air, whenever it found itself any thing indifposed, and was thereby again refreshed, and did not want any other remedy. Affeffor Hast has often inoculated after the method of Baron Dimsdale, and recommends it much; he likewife observes, that the common people have become more inclined to receive the inoculation for their children fince he began with this method, as they then want lefs nurfing and attendance, and are left to their usual liberty, which makes them more chearful and happy. See the narrative of the Prov. Phyf. to Coll. Med. c. i. p. 467 \*.

K 3

Thofe

\* I have thought it fafer, that the perfon on which I inoculated fhould keep a handkerchief on his mouth and nofe, in order to prevent the fleems or exhalations from the variolous matter to infect by that way, and caufe a natural fmallpox. This I find difpleafes Doctor Fr. Cafimir Medicus, in his obfervations, Vol. II. p. 771. I have likewife been of opinion that a phyfician, who has feveral patients affected with the fmall-pox to vifit, ought to change his cloaths intirely before he goes to fee a perfon lately inoculated : and that the inoculated one fhould not fee or come near any one who late has had the fmall-pox, unlefs we, by certain figns in the incifion, judge that the inoculation has fucceeded;

Those who think it more convenient for the dreffing of the incised wound, may, during that time, have a jacket on, with the sleeves flit, and tied at the edges, in that part which answers to the incised wound.

ceeded ; for it is likewife a neceffary precaution to avoid the natural infection. Nay, I have not allowed a perfon lately inoculated to receive letters from a place where the smallpox rages, as I know the contagion has been conveyed in this manner from Upsal to a parish in Nerke, about 100. English miles distant from each other. In consequence of this, 1 think Mr. Sutton and Dr. Dim/dale venture too much in this respect, tho' I ought not to express myself fo of these gentlemen, who have had in this, greater experience than any other perfons. However I cannot reconcile this with what Dr. Dimsdale fays (p. 81, Swedis edition), that he indulged an inoculated perfon to undertake a voyage, but advised him not to enter into any company where he might fpread the contagion by his breath, which had then the stench with which this disease is usually attended (p. 29, 31. ibidem); it may be, that the running matter which is taken from the incifion wound before the eruption does not fmell; but it is very certain that ripe matter has a smell, which therefore might possibly infect notwithftanding the quickness of inoculation ; therefore those who have not injured their organs of fmelling by fnuff, are able to feel and foretell the day when the fmall-pox will ripen : as also to know, by the breath of the patient, if the inoculation has taken effect or not. For the same reason it is a common opinion, that a perfon who has not had the fmall-pox runs a greater risk of being infected, if he visits a patient whose small-pox are ripening. Therefore it was faid, that her Royal Highness the Princess Hedwiga Sophia received the contagion at a vifit, where she happened to go through an apartment, close to which a patient was affected with the small-pox: her Royal Highness, who knew nothing of this, felt however the smell, and immediately put her handkerchief to her mouth and nofe; but the infection had already taken, the got the small-pox, and died 1708. However, it may be possible that the infection of the variolous pus is not volatile, as we find that a cruft of the small-pox, or a dry thread for inoculation, likewife conveys the contagion by inoculating; and in that cafe we should receive the infection only by contact, as in the scab and the venereal disease. balk to an

To

#### AND THEIR REMEDIES.

To have always a plaister on it occasions a confusion, fo that one cannot tell how the inoculated matter operates; the first day after the incision, no alteration is to be found in it, but on the following days the skin at the edges of it begins to appear as it were contracted, grows red, and itches. On the fourth and fifth day a hardnefs will be perceived in it, and the inoculated perfon feels a tenderness in the armpit, a heaviness and pain in the shoulder, and a pale stroke, mark or fcratch is to be feen in the wound; fmall bladders will likewife break out all around it, fometimes in great numbers, and the red fpot grows larger; on the 5th, 6th, 7th, or 8th day (for it happens differently) the inoculated perfon begins to be indifposed, is uneasy, affected with flight spasms, a redness in the face, a heavinefs in the forehead, a pain in the head and back, a nausea and a disposition to vomit. The fever begins, continues for three days, and is most fevere at the end of the third : the fcratch is now dry, and the cruft looks dark and of a lead colour, the rednefs about it is now likewife fpread further \*. The fever is generally fo gentle that the patient can walk about : I commonly order at this time a piece of linen, previoufly well rubbed with camphire, to be fastened to the nightcap, in order to preferve the eyes, by hanging down over them. On the 10th or 11th day after inoculation, or the third from the beginning of the fever, the pustules begin to break out by degrees, and at their éruption both the fever and other fymptoms ceafe : the patient is then free from all danger, the incifed wound begins now to discharge a great deal of matter, and most of all when the pustules begin to dry; for they grow by degrees, become yellow, ripen and scale off, fo that all is over by the 18th or 19th day, and

\* One must not be too forward in judging by one or the other of these figns only, that the inoculation has succeeded; in this point Professor Gatti was mistaken, who concluded from the redness and suppuration in the wound only, that the Dutchess de Boufflers would for the surre be secured against the wariolous contagion. She got a natural small-pox two years and a half after that,

the

the patient has feldom a fingle fcar left after it; rarely any fuppurative fever appears at all, unlefs the puftules are in a greater number; in that cafe it may eafily be fubdued by a gentle purge.

The patient ought to keep the fame diet as is above prefcribed \*, and wants no other medicines than gentle purges, in cafe he fhould not have any ftools by the effect of nature; he may likewife walk about in the room, but muft take care not to ufe too great ex= ercife, efpecially not to move the arm much on which the incifion is made, or to fqueeze it much by a tight drefs, for that will caufe the arm to fwell, grow red and full of bladders : fuch an accident may however eafily be remedied by a purge, and by applications of an unguent of litharge mixed with *flores* Zinci.

The incifion does not heal up fo very foon, for in the fame proportion as the puftules ripen, this wound grows dilated; it is however feldom longer than the incifion was made at first, but fometimes shorter; it likewise discharges at that time a great deal of matter, which has the fame appearance as the *pus* in the pussible therefore we leave it to run as long as it chuses of its own accord, and dress it with dry lint when the discharge or the swelling is too great; it remains open in fome for a couple of weeks, in others it is cured fooner.

\* By the narratives directed to Colleg. Med. we find that an alteration in the diet may be attended with bad confequences (fee p. 14, for the year 1765). Profeffor Bergius inoculated two children of a gentleman, and their fervant girl at the fame time; the former had a favourable fmall-pox, but the fervant girl got a very fevere kind. She confeffed her having eaten flily fait herrings, pork, and fuch other things; both before and after the inoculation. P. 255, in the fame narrative, is mentioned by Profeffor Acrell, with what difficulty a noble young lady was recovered, after having eaten fpinage flewed in a copper veffel which was not well tinned. The caufe would not have been difcovered, had it not been for her governefs and fervant woman being fick from the fame circumkance, and as the fame time,

In

In cafe the inoculation does not fucceed, but the fcratch heals quite up without being open again in fix days, it fhews that the patient has either had the small-pox or never will have this difease, or that the thread for this inoculation has been too old or worn off, or the variolous matter washed off by the blood. In that cafe we ought to inoculate him again, in order that he may not in the mean time receive the natural infection. It is attended with no danger to do this immediately, though fome wait till twelve days are paft.

We need not be alarmed though the inoculated perfon fhould not fall fick at the ufual time. Profeffor Swencke inoculated a youth thirteen years of age, who was an only fon. On the fourth day he felt as it were a trembling in the left arm, for the incifion was performed in that arm only. A cruft already covered the wound; on the fixth day he felt a fmart pain in the arm and in the armpit; the fever began on the eighth day, which increased the ninth, with a head-ach and a pain in the back, and reachings and fweat. These symptoms were only of a few moments duration. On the tenth day he had a flight bleeding of the nofe; no small-pox as yet appeared. His father grew uneasy. Dr. Swencke found at last on the twelfth day, and after having wiped off the pus, five true pocks near the wound and on the edges of it. He neverthelefs applied a new variolous matter into the wound the fame night. The next morning the patient had in the face, loins, and on one of the knees, in all four pocks more, which together with the former, role, ripened, and scaled off. The inoculated wound discharged a great deal of matter for twenty-four days; and the cure was entirely performed. Here we plainly find that the variolous matter which was applied last, did not cause any effect at all, for in that cafe a new fever would have enfued on the feventh day, and a new eruption afterwards, which however did not happen. Befides, we perceive that the fever which arifes from the inoculation does not always happen at the fame time. Four children at Stockholm were inoculated at the fame hour and with the fame matter; neverthelefs one of thefe had the fever two days later than the others. The fmall-pox did not break out fooner than after a fortnight on the daughter

daughter of Lord Dalkeith, and not till after twenty-fix days on a foundling; but fuch inftances are This last had already been infected with the rare. measles. It was neverthless fuccessfully cured of both these diseases, first of the measles, and then of the On Mifs De Grave the variolous fever, fmall-pox. after the innoculation, did not appear fooner than after eleven weeks, but the was during that time not very healthy. See feveral fuch inftances in Kirkpatrick, ch. i. p. 102. It is however better when all happens tolerably early.

Nobody ought to be allowed to wait on the inoculated who is not quite certain they have had the fmallpox. Lady Crifeney nurfed her own children when they were inoculated, as fhe thought fhe had had the fmall-pox before; but the got infected and died. The fame fate attend Lady Vierville, who visited the Duches of Orleans, when the young princefs had the fmall-pox by inoculation. See de Foigny, ch. i.

If the bleeding be neglected in a plethoric perfon, he will be liable to red eyes, and a kind of scarlet eruption, refembling that of the eryfipelas. A great number of puftules are fometimes observed as it were breaking out, but the greatest part is dried away within a fhort time, and only a few ripen and ftand their time. Fat children do not get a greater number of pocks than those who are lean; but those who have a brown complexion are faid to be liable to have more than those who are fair.

With refpect to the fever, feldom any thing will be required but tea and whey. In cafe the fever fhould be fevere, we may bleed the patient, and inject a clyfter. In cafe we chuse to get any thing from the shop, we may prescribe a cooling emulsion with a little nitre in it, and give a tea-cup-full of it every two hours. However, we ought to prepare and get. only a little at once of this, for it acquires the smell of aqua fortis by being kept some time. The cooling draughts which are recommended in the Chapter on Ague are also good, or the patient may drink cold water and fit up. But the best of all is found now to be a purge which is quick in its operation, (as was recommended in the chapter on the small-pox): this we ought

### AND THEIR REMEDIES.

ought to give on the fecond or third febrile day. The violence of the fever will abate as foon as the patient has had some stools by it; and the cruption succeeds, but frequently fo gentle and flight, that the patient doubts himself of its being the small-pox. Nevertheles he is secure from this disease for the future, for when fuch have been inoculated a fecond time, the contagion has not succeeded. Affeffor Bierchen inoculated a young gentleman who was twelve years old, and of a plethoric and reddifh complexion, and a bad temper. He fell fick the usual time, but the fever was very violent, his face of a blood-red colour, and fo profound a drowfiness attended it, that it nearly refembled a lethargy; one was obliged to take him by force out of bed and put his cloaths on, and lead him along in the chamber : cooling remedies and clyfters were administred; the fever continued with equal violence; but after having taken of the before mentioned powder of Cremor Tartari, and Jalap Root, and it having procured some stools, the patient was quite relieved, in fuch a manner as if he had not been fick at all. The eruption was fo infignificant and flight, that the Doctor apprehended the patient liable to a new contagion, therefore he innoculated him again after two months with entirely. fresh pus, and according to the method of Dr. Dimfdale, but the infection did not succeed.

If the inoculated perfon gets a fhooting pain under his breaft, has a head-ach, red cheeks, and a tickling in the nofe, it fhews that he will be affected with a *hæmorrhage* at the nofe, which ought not to be ftopped, unlefs we plainly perceive it to be too violent, fo that it would weaken him. In that cafe we must apply a piece of linen in the nofe made up in a little roll, on which has been fpread a mixture of alum and the white of an egg rubbed together. A clyfter injected will alone gently relieve, as the patient who bleeds is commonly coftive.

The vomiting ought to be ftopped in cafe it is too violent. This may be effected by a clyfter of the common fort, or by fome fmall bags filled with mint and fome faffion, and applied to the ftomach, after having been boiled in wine, and fqueezed out; or we may drink fome warm water: the vomiting will ceafe of

140

of its own accord as foon as the puftules are quite broke out. When children fall afleep during the fever they commonly dream much, and awake in an alarm and a fright, especially if they do not see the person who fat at their bed-fide when they fell asleep; their fright and alarms are banished as soon as we speak to them.

A delirium portends no harm, it goes off foon by a bleeding at the nofe, a powder of *camphire*, or a clyfter. The under lip trembling, fhews that a pukeing or a *naufea* will come on.

If the child has been before affected with convultions, or the dentition happens at the time of inoculation, it will eafily get convultions again, either the first night of the fever, or rather a little before the eruption. This denotes in general a favourable small-pox, is productive of no harm, and may be relieved by a clyster; a camphire powder will be feldom wanted; or one or two grains of mu/k rubbed with ten grains of fugar, and given as foon as the patient can swallow \*. If the patient be uneafy, reftlefs, toffing and agitating his body much, we may give him a little fyrup of poppies towards night, or fome of the elixir paregoricum well mixed with some fyrup, especially that which is made from the Norlandic berries.

If the child be weak, and the puftules will not turn yellow and ripen well, we may give fome bark every third or fourth hour, agreeable to the advice given in the chapter on the Small-Pox and Ague.

When the fmall-pox is dried up and fcaled off, the patient ought to take gentle purges fix or feven times every third or fourth day. He ought likewife to abftain from much nourifhing food, as he otherwife might eafily contract an eruption on the arms and legs, breaft and back, which itches, and on being fcratched,

\* When Doctor Ingenhousz was in Vienna, it happened that a child he had inoculated had the convulsions. He hastened to open the window, and held the child out of it; the convulsions ceased instantly. This case I got by a letter from Vienna, from a person whom I can depend upon.

discharges

### AND THEIR REMEDIES.

discharges an acrid lymph. It would be of service to let children afterwards drink a ptisan of *radix Chinæ*, mixed with a little milk, and continue it a fortnight. Older persons ought to drink a decoction of guaiac, likewise diluted with milk \*.

\* I ought ito answer a great objection made against the inoculation of the small-pox, before I finish the treatise on it. Some have pretended that the contagion is conveyed to other families either by the perfons inoculated, by the phyficians, or by those who attend upon the inoculated; and confequently thereby occasion the small-pox to rage more frequently in a place than it otherwife would. This argument will foon drop, if we confider that the spreading accounts of it have been false. The contagion in the year 1722, and in the months of April and May, did certainly not arife from the inoculation, as that was first performed in the month of August. The contagion at Paris 1762, was not raifed by inoculation, for this operation was first made there in the year 1763. See De Foigny, ch. i. It is not found that any contagion has been conveyed from the hofpitals of inoculation in London or Stockholm. Nor have we any inftance of that kind from any of the other parts of Sweden, where a great number have been inoculated; neither from England, where the inoculation has been performed on feveral perfons, in these latter years. For, during the difease, nobody is admitted into the patient's chamber who has not had the fmall-pox before. We now act more cautiously than they formerly did in England, when the inoculation was at first introduced. Six fervant maids were there admitted to Mr. Batt's children, careffing them frequently during the course of the disease; all fix were infected and one of them died. See Kirkpatrick, p. 119. As foon as the difeafe is over, the room and " clothes of the fick are washed and aired, the doors and windows kept open, and the fcales of the puttules are burnt. It has never been heard of that any one has caught the contagion in the open air. The pocks after inoculation are always less in number, consequently they exhale less contagious vapours. As to the physicians who visit the inoculated, every one ought reasonably to have more honour and confcience than to spread the infection, they being bound both by the nature of their office and their oath, to preferve and not to injure mankind. If they, dur-

The

ing

The contagion of the small-pox may likewife be propagated by applying on any part of the body, either the variolous pus only, or fome dry crufts of the fmall= pox; they should be put next to the skin, and covered with a plaister, in order that the variolous matter may not go off by exhalations, but be conftrained as it were to enter into the body through the pores. In order the better to rub in the matter, we should mix it with some pomatum or unguent, taking care not to mix camphire in the ointment, as that would deftroy its power of infection. This kind of inoculation has likewife been fuccefsfully employed both in England and Leipzig. The following cafes happened in Eng-. land: A man had a very handsome daughter ten years old, whom he loved tenderly; he took fome variolous pus, mixed it with pomatum, and spread it on the infide of his daughter's gloves, on the places which correspond with the interstices betwixt the thumb and

ing the time, visit other families besides those inoculated, they never should neglect to shift their cloaths entirely, noshing-else will be required. His Royal Majesty, our most gracious Sovereign, has likewife this confidence in the physicians in Sweden, for which reason he has been pleased to order that all inoculations should be made under the inspection of a doctor of physic. The nursekeeper, or the attendant on the fick, ought likewife to wash and air his cloaths before he leaves the houfe where he has been attending. When fuch precautions are taken, we may be pretty certain that the contagion from the inoculated perfon can never be conveyed from one house or place to another. But if imprudent and daring youths fhould fusfer themselves to be inoculated, and then walk about in churches, companies, fee plays, &c. and brag that they have been inoculated, they would firike a dreadful terror, especially in those who have not yet had the small-pox; such abuses would make inoculation prejudicial, in cafe there were not means to prevent them. Every one has a right to use a remedy by which he may preferve his life, provided it does not endanger that of his neighbour. Letters from Paris hint that fomething of that kind happened there, which obliged the Parliament to ask the opinion of the Sorbonne and the faculty, whether the inoculation of the small-pox ought to be allowed or not.

the

the fore-finger, and betwixt that and the middle one. She had a gentle fever on the eighth day, and the puftules broke out on the eleventh, being very gentle, and leaving fcarcely a fcar. In the transactions of the Royal Academy of Sciences for the year 1756, Profeffor Bergius relates the following cafe: A child who had a lethiferous fmall-pox was fuckled by its mother during the difeafe, but on her breaft only. The mother was thereby at last infected, but her difeafe was benign, the pustules being crowded around her left nipple only; fome few broke out in the face, but only a fingle one on her body. The infection has likewife been caught by touching with the hand, or on feeling any one fick of the fmall-pox.

It is either by the one or other of these instances that the variolous contagion is conveyed from one to another; as nobody ever gets the small-pox but by infection, every one will find that those are most fortunate who catch it when the body is well prepared beforehand.

# C H A P. XIV.

### On MEASLES.

THE measles are commonly so gentle a disease, that few children die of it if they otherwise have a good nurfing, and no diforder of the breaft previous to it. Neverthless there are instances of its having raged with fuch violence that almost every individual affected by it lost their lives. This is the reason of the ancients having called it Morbilli in Latin, or the little Plague. I imagine the measles to have been of the fame bad kind, which carried off fo many children at Stockholm in the year 1713. A fimilar, if not a worfe kind raged at Vienna in the year 1732, when the greateft part of the perfons affected had a gangrene in the throat, and died on the third or fourth day. Alfo this fort of epidemical disease, which was spread in London in the year. 1762, in the autumn, must have been very lethiferous, as about three hundred perfons died of it weekly. The meafles
